Turtle Bill of Health

ALBANY (AP)—The State Public Health Council has ruled that as of July 1, merchandisers of pet turtles will have to prove to the Dept. of Health that their turtles are free of salmonella baeteria.

NEW YORK POST
7 March 1972

Wildlife Plague[sic]

LAKE APOPKA, Fla. (AP) — A mysterious wildlife plague is spreading through some of central Florida's fresh waters, killing thousands of fish and dozens of birds. Sixteen alligators have also died.

For the first time now, game wardens report finding the bodies of egrets, crows and seagulls as well as extensive shad and catfish kills.

Officials said the path of wildlife destruction, which began a month ago, was edging northward from Lake Apopka through about seven miles of algae-choked canals to Lake Dora.

Game and Fresh Water Fish Commissioner Dr. Earle Frye said he is sending a team of biologists to Lake Apopka—which straddles the Lake-Orange County line — for intensive emergency studies.

"We're concerned the die-off has now extended to other species of wildlife," said Frye.

At first biologists thought the die-off was attributable to alligators eating dead and rotting fish. Then a DDT theory was pursued. But scientists found more pesticide in live and apparently healthy gators than in the dead ones.

NEW YORK POST, WEDNESDAY, JUNE 9, 1971 50

Indict Dealer In Shipping of Alligator Skins

A Georgia businessman was indicted by a federal grand jury here yesterday on charges of shipping 4,788 alligator skins to New York in violation of laws to protect the vanishing reptiles.

A seven-count indictment accused Atlanta merchant Quince Clayton Plott, owner of the Q.C. Plott Raw Fur and Ginseng Co., of profiting from the poaching of alligators. The nearly 5,000 skins he sent here in 1969 and 1970 had a wholesale value of $92,587, the indictment said.

It's a First

U.S. Attorney Whitney North Seymour Jr. said the indictment is the first of its kind in New York and one of the first attempts the federal government has made to prosecute persons defying laws designed to save endangered wildlife.

Seymour said Plott knew the alligator skins "were obtained unlawfully by poaching." According to the indictment, the hides were "taken, transported and sold in violation of the laws and regulations of the state of Georgia."

Could Get 70 Years

Plott was charged with violating the Lacey Act—a federal law banning the interstate transportation and sale of any form of wildlife that is protected under any state law.

If convicted, he could receive a maximum sentence of 70 years in prison and a $70,000 fine.

27 • DAILY NEWS, THURSDAY, MARCH 9, 1972 •

Geological Abstracts

SIR,—The article, "Abstracts Abandoned" (*Nature*, 234, 167; 1971), contains sufficient contradictions and confusion to require comment. The US Geological Survey publications that will be suspended at the end of 1971 are not providing, as indicated by their titles (*Abstracts of North American Geology* and *Geophysical Abstracts*), comprehensive bibliographic coverage of the literature but only about 30 per cent of it. The Geological Society of America's *Bibliography and Index of Geology*, a product of the American Geological Institute's GEO-REF system, publishes over double that amount of deeply indexed and annotated citations in twelve monthly issues plus an annual cumulative author and subject index under hard covers. This was a major consideration in the Survey's final decision to suspend publication in favour of one English-language bibliography that would contain references to the world literature rather than parochial coverage by discipline, mission, or territorial division. Moreover, in conversations between the Survey and AGI prior to the decision, it was agreed that GEO-REF and the GSA Bibliography would increase their coverage at least to include all of the North American and geophysical material heretofore contained in the suspending publications.

The $10 a year price of the *Abstracts of North American Geology* was completely artificial as anyone producing bibliographies must realize. It was originally based on the cost of a print overrun only, beyond the requirements of the Survey's internal free distribution. As such, it was cheaper than Professor Clayton's *Geographical Abstracts* and Dr Howie's *Mineralogical Abstracts*. Had it been priced realistically, it might still be publishing.

As to the $250 price tag on the *Bibliography and Index of Geology*, it is too bad that the geological community has never accepted the value of information as have the chemists, biologists, and physicists. This is particularly unfortunate as the geologists' use of their archival information is much greater than the use made in other disciplines. They may have to accept it in the future or do without when State funding agencies run out of money or patience, or both. In any event, the *Bibliography* is less expensive than the *Bibliographie des Sciences de la Terre*, the only comparable geological publication in the western world, and cheaper by an order of magnitude than the chemical, biological, and physical counterparts.

We, at GEO-REF, work very closely with both the Bureau de Recherches Geologiques et Minières and the Centre National de la Recherche Scientifique, the producers of the *Bibliographie des Sciences de la Terre* and the *Bulletin Signaletique* and have great respect for their publications. Nevertheless, I fail to see the compensation that the combined French-language service will provide for English-speaking geologists. They do not (and will not so far as I know) even satisfy Professor Clayton's passion for abstracts. We are also receiving cooperation in our bibliographic work from CSIRO in Australia and have plans for input from Europe, including an exchange with BRGM and CNRS. We would welcome a contribution from the UK, but it would have to be of better quality than one we received from there in 1967 and 1968.

Finally, may I call to your attention that the GEO-REF bibliographic service not only produces the printed *Bibliography and Index of Geology*, but it is the only comprehensive service in geology (in any language) that is distributing tapes to data centres, libraries, and universities for computer searching. We are also providing the annual indexes for a dozen primary journals, producing ten volume cumulative indexes for certain serials, and are providing the material for special topical bibliographies such as the *Bibliography of Coal in Kentucky*, published by the Geological Survey of Kentucky, and the *Bibliography and Index of Micropaleontology* which is being published monthly by the American Museum of Natural History. We are seeking further uses of our tape file and are formulating plans for inputting the historical data of geological literature starting in the mid-nineteenth century.

Yours faithfully,

JOEL J. LLOYD

ADVICE TO AUTHORS

HERPETOLOGICAL REVIEW publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals. Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome.

FORMAT. Manuscripts should be type-written on white bond paper, one side only. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and the animal group(s) included. Use standard abbreviations for journals.

The 1971 YEARBOOK OF HERPETOLOGY (published by HISS) contains a list of American Standard abbreviations for some 2,500 journals. Other publications that will be of assistance in the preparation of manuscripts are:

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES (see information on this page).

Common names for North American amphibians and reptiles (COPEIA 1956(3): 172-185).

SCIENTIFIC WRITING FOR GRADUATE STUDENTS, by F. Peter Woodford (Rockefeller Univ. Press, New York, NY 10021). $5.75.

STYLE MANUAL FOR BIOLOGICAL JOURNALS (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, DC 20016). $3.00.

A publication that will be found helpful in planning and producing adequate illustrations is:

A HANDBOOK OF BIOLOGICAL ILLUSTRATION, by Frances W. Zweifel (University of Chicago Press, 58th Street at Ellis Avenue, Chicago, IL 60637).

Line-cuts are photo-offset directly with the text, and should have widths of 4 1/4 inches (one column) or 9 1/4 inches (two columns). Each line of illustration equals six lines of text (full page copy length is 12 3/4 inches). Line cuts are reduced about 25 per cent in processing.

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

P A G E C H A R G E S AND REPRINTS

Authors of articles or reports submitted to H R are asked to contribute toward their publication costs to the extent of $20 per page. This payment is not a prerequisite to publication. However, paid articles receive priority and are likely to appear earlier than others.

Page-charge payments entitle the author to 100 reprints (or tear-sheets) without additional charge. /Additional reprints may be purchased at $5/page/per 100 copies./

Cost-sharing of this kind allows additional publication without increasing H R's cost to Society members and subscribers. It is, thus, a method of holding dues and subscription rates at their present levels.

CHANGE OF ADDRESS

HISS now handles the mailing lists for:

THE SOCIETY FOR THE STUDY OF

AMPHIBIANS AND REPTILES

THE HERPETOLOGISTS' LEAGUE

and the

VOLUME 4, NUMBER 1
FEBRUARY 1972

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Society was founded in 1958 as the OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

The SSAR encourages the acquisition of knowledge on amphibians and reptiles, and the dissemination of scientific information of these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communication between amateur and professional workers. (See Third Cover for membership information.)

HERPETOLOGISTS

LEAGUE

The Herpetologists' League is an international organization which was established in 1936 by Major Chapman Grant. It is dedicated to furthering knowledge of the biology of amphibians and reptiles.

In 1971 it had 900 members and fellows (including Life and Honorary members), and more than 400 institutional subscriptions to its journal, HERPETOLOGICA, which has been published continuously since 1936.

All persons interested in herpetology are eligible for membership. (See Third Cover for membership information.)

EDITORIAL

Something of a new look is introduced with this number of HERPETOLOGICAL REVIEW. Most of the differences from previous issues are intentional. One is unintentional.

To get the latter out of the way first, the CURRENT HERPETOLOGICAL TITLES section is omitted from pressure of circumstance. During the last half of 1971 the various dock strikes held up receipt of foreign journals, causing us to publish a number of short lists. When the New York strike ended, we were so inundated with such journals that they held up final processing of the list for HR 4(1), and amplified it to something more than 40 pages of titles alone. It seems better, therefore, to go ahead with the publication of articles and news items in this issue, and to reserve HR 4(2) mainly for "current titles."

You also will notice the absence of UNREVIEWED-UNEDITED COMMUNICATIONS. This is not accidental, but was voted by the SSAR Board in August. It was the majority belief that this experimental section, though appreciated by many, might tend to draw research articles that could better be published in established journals.

However, the HR format introduced here does provide for the reporting of data (as distinguished from research studies) in a number of different sections. It also reflects some of the suggestions that came in with last year's poll of members.

We would like to run more NEWS of individuals and institutions. In order to do this, however, we must have individuals that will send in such news. Fortunately, there is considerable news from regional societies that can be reported in this issue. We are happy also to report the establishment of three new special sections.

HARVEY POUGH (Cornell University) has agreed to edit a section of PHYSIOLOGICAL MISCELLANEA in the general style of George Zug's GEOGRAPHIC DISTRIBUTION section. He will attempt to consolidate information on such things as temperature records and activity periods, and to publish them in a concise form.

A similar section on LIFE HISTORY DATA, in which we hope to consolidate brief reports on laying and birth dates, clutch sizes, and other critical data of this sort, will be edited by HARRY GREENE, of the University of Texas at Arlington.

A somewhat different section is HERPETOLOGICAL HUSBANDRY. We have discussed the initiation of an animal care section for some time, and it is finally introduced with this issue. We hope to have contributions from many different sources for this section, and we intend to offprint the best ones for wider distribution to the public -- and for possible later collation into a handbook. This section will be edited by JAMES MURPHY of the Dallas Zoo.

Finally, a general REPORTS section will continue to publish data on techniques, karyotypes, and other subject material not included in the special sections.

We invite contributions to, and comments on all of these sections. -- HGD.

The Herpetological Review
American Museum of Natural History
Central Park West at 79th Street
New York,New York 10024

Dear Sirs:

The phrase "unreviewed - unedited" is a bald-faced, flat-out lie.

My paper on triploid Ambystoma was reviewed in detail by at least Dr. H. G. Dowling, who required me to cut it to make it acceptable for publication. It was severely edited in terms of layout, especially messing up the section of my summary arguments.

And to what avail? To save space? To save space for a block print of an imaginary lizard centered in a near-empty column? Idiocy!

You guys should stick to counting scales and get a real editor. With a sail like you, who needs an anchor?

Sincerely yours,

James D. Lazell
Staff Herpetologist

SECOND REPORT FROM THE JOINT COMMITTEE

FOR COOPERATION OF THE HERPETOLOGISTS' LEAGUE

AND SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The committee met for a total of seven hours on 27 and 29 December 1971 during the AAAS meeting in Philadelphia. A detailed analysis of the financial records of both societies showed that each had ended the year in good financial condition. A lengthy examination of financial models and possible dues structures of an amalgamated society revealed that financial considerations alone would not prevent a merger and that an amalgamated society could be operated on a sound monetary basis to provide continued services to the herpetological community.

The committee recommended that all present publications of the two organizations be retained with HERPETOLOGICA as the major journal for papers and the JOURNAL OF HERPETOLOGY as a serial for the possible publication of monographs and taxonomic papers. Three categories of memberships and dues were suggested: Sustaining, to receive all journals; Regular, to receive HERPETOLOGICA, HERPETOLOGICAL REVIEW, and possibly the facsimile reprints; and Associate, HERPETOLOGICAL REVIEW. The middle category of membership would be structured to provide equal or increased services to present regular members of the two societies. The committee recognized the moral commitment to continue services to life members; those holding life membership in only one society would receive the services of regular membership and persons holding life memberships in both societies would receive the service of sustaining membership in a merged organization. We must emphasize that no final recommendations on dues and membership categories have been made, but are under intensive study. Detailed recommendations will be presented in later reports, with a final report to be given at the Lake Texoma meeting in August and published in the following issue of HERPETOLOGICAL REVIEW.

The important philosophies and "intangible attributes" of the present societies were discussed and the committee agreed that the best of these must be continued in any new organization. For example, the unwritten but recognized policy of SSAR to hold late summer annual meetings at locations where low costs would encourage students and non-professionals to attend must be continued. Paper sessions and council meetings at other times of the year could also be scheduled to coincide with national or regional meetings of other societies. Sincere efforts to provide services to regional herpetological societies and to encourage participation of non-professionals would be made by an amalgamated organization. The committee believes that one society representing herpetology could speak with a stronger voice on conservation and similar matters of interest to the membership.

The alternatives to formal merger are many. These include a continuation of the two societies with the present level of cooperation, with increased joint efforts, or with no combined undertakings. There are obviously many pros and cons to a merger and the committee will attempt to outline these in the next report due to be published in the next issue of HERPETOLOGICAL REVIEW. At this time the majority of the joint committee believes that a merger is feasible and that continued study of the details is required.

A panel discussion on the pros and cons and the details of a merger will be held at the Lake Texoma meeting on 15 August. Within one month after the meeting a ballot will be sent to the memberships of both societies for vote on amalgamation. A merger would take place on 1 January 1973 only if a majority of the membership of each society approved. A nomination committee from the two societies would present a ballot for officers for the new organization. The proposed constitution and by-laws, details of membership categories, the operating philosophy, and pros and cons will be provided to the memberships by publication in HERPETOLOGICAL REVIEW or by direct mailing prior to any formal vote.

The committee continues to solicit comments, questions and expressions of concern on any item to be considered in a possible amalgamation. These may be sent to the Chairman or to any committee member.

Kraig Adler, Herndon G. Dowling, Robert E. Gordon, Hobart F. Landreth, Clarence J. McCoy, Henri C. Seibert, Wilmer W. Tanner, and Victor H. Hutchison (Chairman).

MEETINGS AND SOCIETIES

CALENDAR 1972

9-14 April....FEDERATION OF AMERICAN SOCIETIES FOR EXPERIMENTAL BIOLOGY, 56th Annual Meeting, Atlantic City, NJ.

13-17 April....SOUTHWESTERN ASSOCIATION OF NATURALISTS, Annual Meeting, Texas Tech. University, Lubbock, Texas.

18-23 June.....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Boston.

July.....SALAMANDER SYMPOSIUM, Highlands Biological Station, North Carolina.

14-17 August...Combined Meeting: HERPETOLOGISTS' LEAGUE and SOCIETY FOR THE STUDY OF AMPHIBIANS and REPTILES, University of Oklahoma Biological Station, Lake Texoma.

September....INTERNATIONAL SOCIETY ON TOXINOLOGY, General Meeting, Institute of Organic Chemistry, Darmstadt, West Germany.

24-30 September...INTERNATIONAL CONGRESS OF ZOOLOGY, Monaco.

26-28 December....HERPETOLOGISTS' LEAGUE, Annual Meeting (Cosponsored by the SSAR), Washington, D.C. (with AAAS).

CALENDAR 1973

June....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, San Jose, Costa Rica.

4-11 August....FIRST INTERNATIONAL CONGRESS OF SYSTEMATIC AND EVOLUTIONARY BIOLOGY, Boulder, Colorado.

CALENDAR 1974

June....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Ottawa, Canada.

NEIL D. RICHMOND has been named Curator of the newly-established Section of Environmental Studies at the CARNEGIE MUSEUM. This section will function as an ecological and environmental information center, and a coordinating agency for ecological studies. CLARENCE J. McCOY replaces Richmond as Curator of the Section of Amphibians and Reptiles.

JOSEPH F. GENNARO has been awarded tenured status at NEW YORK UNIVERSITY.

The AMERICAN MUSEUM OF NATURAL HISTORY again invites applications for small grants to cover investigations on the North American fauna. Most of the awards have been made for support of field work, but trips to study collections at the AMNH are also supported. Application forms can be obtained from:

Theodore Roosevelt Memorial Fund, AMNH
New York, NY 10024

JAMES R. GRISSOM (Arkansas State Univ.) received his M.S. degree in 1971 with a thesis on, "Electrophoretic Study of Serum Proteins in certain Plethodon Salamanders."

KENNETH R. PORTER (Denver Univ.) is studying a population of Rana pipiens with a high incidence of blue individuals.

RICHARD M. BLANEY (Louisiana State Univ.) received his Ph.D. degree in 1971 with a dissertation on the systematics of the kingsnake, Lampropeltis getulus.

RICHARD THOMAS (LSU) visited Peru and Haiti in his continuing studies on Antillian typhlopid snakes.

GARY EBERLY (LSU) is studying the chromosome morphology of New World natricine snakes.

CRAIG JURATSCH (Lab. Neurological Research, Univ. Southern California, Los Angeles) is conducting work on immunity in snakes to various snake venoms in an attempt to determine the cellular mechanism involved.

RICHARD SCHAEFFER (LNR, USC) is studying the enzymatic components of snake venom glands (especially crotalids).

FRED BUESS (LNR, USC) is conducting studies on the definitive mechanism by which crude Crotalus venoms produce their deleterious effects on hemodynamics.

JACOB DUBNOFF and FINDLAY E. RUSSELL (LNR, USC) are conducting a series of physiopharmacological and biochemical studies on the proteins and peptids of the venom of Crotalus viridis helleri.

JOB OPENINGS

We are looking for new staff members to broaden our faculty resources in animal ecology and limnology. The areas in which we are especially interested are the following: systems ecology; animal ecology with a background in HERPETOLOGY, or in soil invertebrates; limnology with special interest in aquatic systems, or in plankton, or in water physics and chemistry.

The appointments will probably be made at the rank of Assistant Professor in the Department of Zoology and Entomology. The responsibilities of the new members will include teaching in general ecology and related courses at the undergraduate level, participation at times in the introductory course of General Biology or General Zoology, and teaching and supervision of graduate students in our interdepartmental Graduate Program in Ecology. His research program will be one of his own choice.

I will appreciate your cooperation in notifying suitable individuals of these opportunities. Please advise any person who is interested to write me, sending a summary of his background, experience, and interests.

James T. Tanner, Director
Graduate Program in Ecology
UNIVERSITY OF TENNESSEE
Knoxville, TN 37916

MEMBER'S DESIDERATA

TIMOTHY S. DOYLE (Autumn Lane, Carlisle, MA 01741) would like to hear from readers who have seen or collected "double" turtle eggs (one egg, the size of two hitched together), especially those of Chelydra and Emydoidea. He is also anxious to acquire hatchling or young specimens of Emydoidea blandingi for use in a growth study. A trade or purchase can be arranged.

TIMOTHY S. DOYLE

Autumn Lane
Carlisle, MA 01741

PRELIMINARY ANNOUNCEMENT

J O I N T M E E T I N G

SOCIETY FOR THE STUDY OF AMPHIBIANS
AND REPTILES
and the
HERPETOLOGISTS' LEAGUE
14-17 August 1972

The Annual Meeting of the Society for the Study of Amphibians and Reptiles will be held at the University of Oklahoma Biological Station at Lake Texoma from 14-17 August. The meeting will be co-sponsored by the Herpetologists' League. The theme of the meeting will be "The Future of Herpetology," and a panel discussion on the feasibility of an amalgamation of the two societies will be an important part of the sessions.

The evening of 14 August has been reserved for board and committee meetings, a beer social will be held on the evening of 15 August, and a banquet on 16 August. Paper sessions will be scheduled during the day on 15 and 16 August, and field trips will be organized for 17 August. The costs for those attending will be $7.50 pre-registration ($10 at meeting), $8.00 per day for room and meals, and $5.00 per day for meals only. The costs of the social and banquet are included in the registration and room fees.

Rooms for families and couples are very limited and members are urged to consider camping at nearby campgrounds. Shower and sanitary facilities of the Biological Station will be available for campers.

Registration forms, calls for papers, and detailed information on the meeting will be published in the April or June issue of HERPETOLOGICAL REVIEW.

The local committee for the meeting consists of Drs. Hobart Landreth, Charles Carpenter, and Victor Hutchison (Chairman), University of Oklahoma, Norman, Oklahoma 73069.

EASTERN SEABOARD SOCIETIES

FIRST JOINT MEETING OF THE EAST COAST HERPETOLOGICAL SOCIETIES

On October 9, 1971 more than 180 delegates and members representing herpetological societies from the Virginias to Boston assembled at the Staten Island Zoo in New York to attend the first EAST COAST HERPETOLOGICAL SOCIETIES CONVENTION. Carl Kauffeld, Director of the Staten Island Zoo, served as host and the New York Herpetological Society served as the sponsoring organization.

Carl Kauffeld in his welcoming address, emphasized that the conservation role of our societies is one of the main reasons for their existence. Speaking of today's larger reptile societies Mr. Kauffeld warned that with an increase in the number of "fans" there could be an increase of danger to what we want to protect and study. His advice is to keep the number of specimens down, NO OVER-COLLECTING! Exhibit an empty case with the label reading "Extinct" or "Almost Extinct", rather than show off an almost extinct specimen in a collection. It is a matter of self-discipline, Mr. Kauffeld stated.

Robert Tuck, President of the Maryland Herpetological Society, represented the two Virginia herpetological societies and the M.H.S. Mr. Tuck, working on legislation for endangered species has formed a "Bog Turtle Committee," which is studying the status of this species, which is especially threatened by the destruction of its habitat and over-collecting. Mr. Tuck intends to present his ideas to his Congressman.

Malvin L. Skaroff, President of the Philadelphia Herpetological Society, stressed the importance of legislation for endangered species in Pennsylvania and New Jersey. "The P.H.S. is still alive and well," Mr. Skaroff stated, announcing that the next issue of the PHS-Bulletin would be in print soon. The PHS has worked out a plan to aid the new Reptile House of the Philadelphia Zoo in the purchase of live specimens. Mr. Skaroff asked other societies to join the fund-raising for the zoo's collection.

The Connecticut Herpetological Society was represented by George T. Vesper, President, and 15 members. One of the plans of the C.H.S. is to arrange a Herp Show for the public in a public institution. Mr. Vesper suggested the establishment of a bulletin exchange program within the regional societies.

Dave Hulmes, President of the New York Herpetological Society, introduced Ernst G. Hofmann as Senior Editor of the NYHS Bulletin "Herp". Ernst Hofmann pleaded for more active participation of the membership body in submitting articles, illustrations and photos for HERP. Dave Hulmes briefed the audience on the society's educational program in New York City Schools. The 1971 presentation of the program was again highly rated by the education administrators and teachers. This type of work is an excellent way to introduce students and teachers to herpetological conservation ideas. The NYHS is planning to expand the program to other school districts in New York and New Jersey.

Dr. Herndon Dowling, Director of Herpetological Information Search Systems (HISS), spoke on the "Crisis in Herpetological Literature Today". Dr. Dowling expressed the need for closer cooperation between professional and regional societies. In 1971 over 4,000 articles and papers published throughout the world were screened and sorted for the IBM and microfilm files at the HISS office at the American Museum of Natural History. The proposal for 1972 is to provide and initiate specific information service in Herpetological Review, co-sponsored by the Herpetological League and the SSAR, to form a "National Newsletter". The HISS program, supported by the National Science Foundation, is in need of support by the regional societies. The availability of herpetological information and literature is a vital factor in the research operations of regional societies.

John Behler, Assistant Curator of Reptiles at the Bronx Zoological Park, spoke on "Endangered Reptiles and the Law". It is the crime of our ancestors to have committed this ecological plunder for commercial interests in the name of (shortsighted) "progress," Mr. Behler stated. A Corps of Engineers with sophisticated tools, expert land developers and pesticides have created ecological destruction to promote the human population explosion.

Mr. Behler showed figures from the 1969 records on imports of exotic animals into the U.S. Tropical fish imports hold the top with 73,000,000. Second are the reptiles with 1,390,000 and amphibians appear with 400,000 on the list. The combined figures on mammals and birds stand at approximately 1,500,000. Aside from these legally-imported live animals, it is estimated that at least 10% can be added for animals which entered the states illegally.

The importation of mammalian and reptilian hides is still going strong, although valid export permits from the country of origin are required. The problem lies in the lack of qualified inspection personnel at the entry ports. It is almost impossible, even for an expert, to determine the species by examining a crocodilian hide. There is reluctance by the fashion industry to accept regulations or impose restrictions on a voluntary basis because of the fear of competition among themselves. Only an alert public can avoid the slaughter of endangered species by refusing to buy the products fashioned from these animals! Mr. Behler's

talk was most informative and followed by a lengthy discussion with strong statements by the audience.

After a break for dinner, the Staten Island Zoo's reptile wing was opened for a viewing of the fine collection of reptiles and amphibians. When all were reassembled in the auditorium, the program continued with speakers representing several of the participating societies.

Robert Tuck, Jr., President of the Maryland Herpetological Society, and staff member of the Smithsonian Institution, took us to the Caribbean. First to Jamaica, in quest of the rare tree frog Hyla lichenata. After many hours of tracking and listening, and a few bumps and bruises, one of the elusive giants was captured. The next stop was Tobago where more interesting reptiles and amphibians were photographed and perhaps a new species of frog discovered by Mr. Tuck.

Finally we climbed El Touche in Trinidad to find the beautiful little frog Amphodus auratus. This frog is now endangered due to the destruction of its very limited habitat, a certain type of bromeliad found on that mountain in Trinidad. Bob's amusing anecdotes were a pleasure to all.

Dr. Norman Scott, Professor of the University of Connecticut and advisor to the C.H.S. followed by taking us to the country of Costa Rica, a land of varied terrain and climate. We were shown the almost temperate deciduous forests of the northwestern area and the tropical rain forest of the southern and Caribbean slopes. Dr. Scott's superb color slides illustrated the great variety of amphibians and reptiles in this beautiful country.

To bring this most eventful day to a close, we returned to our own southeastern area. Robert Zappalorti, staff member of the Staten Island Zoo, representing N.Y.H.S., guided us through the Okeetee Preserve in South Carolina. Bob, being aware of the great need to conserve our indigenous fauna, collects and relocates every year countless numbers of snakes of various species found in the area. The snakes are collected in the open burned sections and released in the unburned areas where they can take cover, thus being protected from capture by the vast number of collectors that invade the preserve every spring. Bob's excellent selection of color slides illustrated the work of a conservationist trying to preserve an area rich in species of reptiles and amphibians, but with fewer specimens seen each year. His kind of "collecting" will assure that the snake enthusiast of the future will be able to observe a beautiful Corn snake, Scarlet kingsnake, or perhaps a large Diamondback rattlesnake in its natural habitat.

So ended the First East Coast Herpetological Societies Meeting. (From notes for NYHS BULL 7(3/4)).

GROUP AT THE STATEN ISLAND MEETING. -- Top (L to R): Ron Reeves (2nd VP, NYHS); George Meyer (Treas., NYHS); Malvin Skaroff (Preas., PHS); Robert Tuck, Jr. (Pres., MHS); Herb Herman (Advisor, NYHS); Jeremy Jacobs (Secty., MHS); Peter Wemple (VP, MHS). Bottom (L to R): Rene Katz-Braunschweig (Advisor, NYHS); H. G. Dowling (Advisor, NYHS); George Vesper (Pres., CHS); Dave Hulms (Pres., NYHS); John Behler (Asst. Curator Herpetol., NYZS); Norman Scott (Advisor, CHS); Itzchak Gilboa (HISS).

JOINT MEETING OF EASTERN SEABOARD HERPETOLOGICAL SOCIETIES, HERPETOLOGISTS' LEAGUE and S.S.A.R.

On December 28, 1971 approximately 200 people attended a meeting sponsored by the Philadelphia Herpetological Society at the New Reptile House at the Philadelphia Zoo. Timed to coincide with the annual meeting of the Herpetologists' League and the Society for the Study of Amphibians and Reptiles, the meeting called together the Philadelphia, Maryland, New York, Virginia, Northern Virginia, and Connecticut Herpetological Societies.

After greetings by Dr. Roger Conant and representatives of the various societies, Dr. Wilmer W. Tanner, President Herpetologists' League, Dr. Robert Gordon, Chairman, SSAR, Robert Tuck, President, Maryland Herpetological Society, Frank Watrous, President, Virginia Herpetological Society, Ted Feuerback for North Virginia Herpetological Society, and Malvin L. Skaroff, President of the Philadelphia Herpetological Society, there was a tour of the new reptile facility. Lunch was served by PHS, after which all returned to the Benjamin Franklin Hotel where a session was held for the reading of scientific papers.

On Wednesday a business meeting was held, at which time a report was given on the proposed merger of SSAR with the Herpetologists' League. There will be other joint meetings at the University of Oklahoma Biological Station, Lake Texoma, Oklahoma in August 1972, and at Washington, D.C., in December 1972.

This was an occasion where the professional and local or amateur societies met together in a good cooperative spirit. We hope that such cooperation may continue and become quite fruitful in days to come. - MLS.

MICHIGAN SOCIETY OF HERPETOLOGISTS

Before I had a chance to report about the activities of the Great Lakes Herpetological Society, it became extinct. I was informed in a recent letter from the president of the Michigan group (Horace G. Stafford, MSH, 754 W. Shepherd St., Charlotte, MI 44813) that their new group is active and organized. Here are some of their activities. They are devoted to the study, appreciation and preservation of amphibians and reptiles. It is an homogenous group in which long-haired college men serve on committees with older, retired gentlemen without a trace of a communication gap.

People join for two reasons: interest in keeping live specimens and/or interest in research. Those who join as keepers eventually find themselves intrigued and active in research projects.

Their biggest all-member undertaking now is to locate and record data on a residual colony of the Red-bellied Watersnake, Natrix erythrogaster neglecta which is located in Calhoun County. This is being done at the request of Dr. Sherman Minton of Indiana University. They are classifying and narrowing down information given by Dr. Speare of Olivet College, Dr. Hensley of Michigan State University, and Dr. Charles Walker of the University of Michigan.

The group runs six school programs in Michigan for science classes which have resulted in a changed attitude of hundreds of young people towards herptiles. They use live specimens, and spend the majority of the time encouraging youngsters and answering their questions.

Members can borrow periodicals and books from the Society library, and in fact, two junior high students, Bill Zajac and Tim Hey, seem to have memorized most of Conant's Field Guide.

Horace G. Stafford and Bob Hickman are working on a set of study plans which they want to present to the biology teachers of Michigan at their meeting this spring at Mt. Pleasant.

All these activities are starting to press the Society financially because travel expenses come from the personal resources of the individuals who volunteer for the particular project. I hope that a new amalgamated national society will be able to provide the necessary aid in guidance, monies, films and speakers to a group so active and fulfilling so important a niche. - IG.

KENTUCKY HERPETOLOGICAL SOCIETY

The KENTUCKY HERPETOLOGICAL SOCIETY is a young organization. It was formed in the spring of 1969 in the Louisville area. Monthly meetings with planned programs are held on the third Sunday of the month at the Louisville Zoological Gardens. The Society publishes a monthly newsletter named, The Kentucky Herpetologist.

The Society's primary goal is the conservation of Kentucky's herpetofauna. Working toward this goal, the KHS has been involved in various activities, including giving numerous educational talks to small groups and participating in programs on the local educational T.V. network.

Working with the Kentucky Humane Society and the Louisville Zoological Gardens, the KHS has sought to aid those reptiles and amphibians which are held captive. When captive animals are received, local species are released into a congenial habitat, and homes are found for exotic specimens. The Society also tries to help captive herps by giving advice and assistance to their keepers.

Other activities of the KHS include field trips and social get-togethers. Public displays of living specimens are set up sporadically with the cooperation of area schools and merchants. Efforts are also made to aid individuals working on research projects.

Membership in the KHS is open to any individual seriously interested in herpetology. Individual dues are $3.00 per year ($2.50 for students). Visitors are always welcome at meetings. For further information, contact either William T. Mobley (935-4393) or Eddie M. Ashmore (968-6548) or write: The Kentucky Herpetological Society, c/o Eddie M. Ashmore, 5303 Barnes Drive, Louisville, Kentucky 40219.

HAPPY BIRTHDAY TO YOU, NVHA

The Northern Virginia Herpetological Association, now 3 years old, was formed to provide an opportunity for persons concerned with herpetology to further their interests in association with other like-minded individuals.

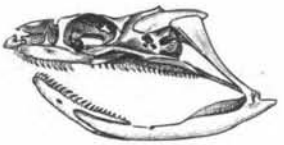
Meeting once a month, NVHA attempts to address itself to all phases of herpetology. All taxonomic groups and geographical areas fall within the Association's scope. Though meeting in the northern Virginia area, the organization welcomes members from throughout Greater Washington. Interested younger people are encouraged to join. Open to all age groups, the Association particularly welcomes those individuals having a more mature interest in herpetology.

NVHA is especially concerned about informing its members and the general public as to the nature and significance of reptiles and amphibians, their role in the environment, and the need for conservation. Proper care in captivity, as well as the natural history of wild populations, is dealt with. Since a major role of the group is education, interest and enthusiasm are the major prerequisites for membership; there is no need to be a specialist in the field.

The meetings provide a structure for the active interchange of information. Guest speakers and members of the Association present frequent programs. In addition, there are "clinic" sessions aimed at solving problems related to captives, including feeding and disease problems and assistance in identification. Current literature in the field and many other subjects are discussed. Field trips for observation purposes are scheduled when practicable. A Bulletin, which appears at irregular intervals, is free to members.

For additional information write to: Frank T. Watrous, 1201 S. Court House Rd., Arlington, VA 22204

BUTTE COUNTY T & T ASSOCIATION



"...There is a new Northern California Club -- it is the Butte County Turtle and Tortoise Association. They meet on the Chico State College Campus. When in the Chico area, call Sean McKeown at (916) 345-6527 for information, or leave your name and phone number with the Secretary for the Department of Biological Sciences at Chico State College...."

Their Notes and Announcements is called "Turtle Droppings." The first meeting was held September 24 and was an overwhelming success. Dan Emery, Secretary, gave a presentation and slide show on "Color Variation in the Northwestern Pond Turtle (Clemmys m. marmorata)." George Green, member from Arbuckle, CA, initiated a project to inform dorm coeds as to proper techniques in care and feeding of the baby pet turtles they keep in their rooms. Among these are: common sliders (P. s. elegans) and P. c. concinna, the river cooters. Club members are setting up a box turtle exhibit in the Biological Sciences Building.

No notes on dues or frequency of publication of meeting notes were made, but get in touch with this new association through Sean McKeown, President, Butte County Turtle and Tortoise Assoc., 112 Shasta Hall, Chico, CA 95926. (from Tortuga Gazette).

FILMS AND LECTURERS

I have received a number of requests from groups new and old, to provide and advise on availability of films and lecturers as suitable programs for regional society's meetings.

Speakers bureau

For a continuing viability of the various regional societies, it seems obvious that the most important thing necessary is the regular presentation of interesting and informative programs at meetings. I feel that by capitalizing on SSAR and HL membership in the same region, we can make willing and qualified lecturers more readily available for the meetings of the regional societies. If you are willing to speak or present a program to a group in your area, please let me know your name, address, telephone numbers and your topic. We expect that in the future most of these groups will be able to at least reimburse travel expenses.

Film service

If you have your own good quality films or you know of available films please let me know the title, from whom it is available, specification (8 or 16 mm, black or white or color, sound, etc.) running time, and rental cost. -- I. Gilboa, HISS.

FIGURE. Dendrobates pumilio, adult male calling while "in hand." [Photo by Franco Peñalba, courtesy of Jaime Villa.]

My thanks to all those who kindly sent me publications and news items. I am sorry that we are not able to include all of them this time. Please keep them coming. - I. Gilboa.

MARYLAND HERPETOLOGICAL SOCIETY

MEETING SCHEDULE: 1972

All meetings and field trips are open to the public, and anyone interested is cordially invited to participate.

Meetings are held at the headquarters of the Natural History Society of Maryland, Inc., 2643 North Charles Street, Baltimore, Maryland 21218, beginning at 10:00 AM on the third Saturday of October thru March. Field trips leave from the same address at 8:00 AM on the third Saturday of April thru September. Steering Committee and Business meetings (open to everyone) are held at the same address, beginning at 8:30 PM on the first Wednesday of March, June, September, and December.

19 February....Speaker - Mr. Craig Phillips, Assistant Curator, United States National Aquarium. "Exotic amphibians and lizards introduced into the Miami, Florida, area"

18 March....Speaker - Mr. Christopher H. Dodge, Biologist, U.S. Navy (update on his research into turtles and gravity).

15 April....20 May 1972; 17 June 1972: Field trips to selected areas in Maryland.

15 July....East Coast Herpetological Societies combined meeting in the Baltimore-Washington area; to be sponsored by MHS

19 August....Field trip to selected areas in Maryland

16 September....Field trip to selected areas in Maryland

21 October....Speaker - William Marvel, Art & Culture Columnist, National Observer (gartersnakes as a hobby).

18 November....Speaker - to be announced

16 December....Speaker - F. Prescott Ward, V.M.D., Research Veterinarian, Edgewood Arsenal, Department of the Army (update on research on the amphibians and reptiles of Carroll Island, Maryland).

(Steering Committee and Business meetings will be held 1 March, 7 June, 6 September, and 6 December.)

CTTC - WESTCHESTER

The WESTCHESTER CHAPTER of the CALIFORNIA TURTLE AND TORTOISE CLUB (Alondra Park Headquarters Bldg., 3850 Manhattan Beach Bl., Lawndale, California) is planning to purchase some land on which to set up a (primarily) tortoise preserve. A good-sized sum of money has been earmarked for this project by an interested member. Tentative plans are to have accommodations for someone to be on the property most of the time. Also, planning calls for some area where holding pens can be erected for the purpose of acclimating tortoises gathered up to be set free eventually. More about this as plans develop.

BACK ISSUES

The Southwestern Herpetologists Society publishes a monthly NEWSLETTER, a quarterly magazine, HERPETOLOGY and an annual journal, HERPETON. HERPETOLOGY contains articles pertaining to reptiles and amphibians by members and interested contributors. HERPETON features papers of an original and scientific nature and should be of value to all herpetologists. Both HERPETON and HERPETOLOGY are available for $.50 each. Write for order blank and list to: Herpeton-Herpetology, P.O. Box 2054-D, Pasadena, CA 91105.

D E A L E R S ?

The following dealers in California listed below have been advertising reptiles and herpetological supplies for sale in several leading nationally circulated magazines during the past year. These dealers operate only under postal box numbers, names, or street addresses. They all claim to be members and recommended dealers of the "American National Herpetological Society." The NYHS urges persons who have had contact with the organizations listed below to write their experiences and comments to Dave Hulmes, President, P.O. Box 3946, Grand Central Station, New York, NY 10017.

WORLD WILDLIFE FUND

The World Wildlife Fund is expending a great deal of money in conservation projects, many of which are of herpetological interest. It seems strange that the herpetological societies have no voice in the projects selected or the monies allocated.

The following selection gives some indication of the projects and funds currently involved (From ANIMALS 13(17): 814-815).

	BUDGETED FUNDS
MARINE TURTLES -- Survey on Southeast African coast	2,566
TORTOISE, Testudo yniphora, Madagascar -- Biological survey to prepare conservation measures	1,306
MORELET'S CROCODILE -- Propagation in captivity in Mexico	2,704
NILE CROCODILE, Ethiopia -- Assessment of resources and management program	1,176
ENDEMIC IGUANA of Anegada, British Virgin Islands -- Contribution to Conservation	4,308
GALAPAGOS ISLANDS, Ecuador -- Educational leaflet	14,436
Evaluation of tourist impact and management	6,874
Tortoise rearing	2,703
Study of effects of introduced mammals	7,796
Control & eradication of introduced mammals	10,770
Maintenance of Charles Darwin Research Station	3,665
SEA TURTLE RESOURCES, Western Australia -- Conservation prog	5,137
HAWKSBILL TURTLE -- Conservation in Queensland	5,137
MADRAS SNAKE PARK, India -- Establishment	2,708
IUCN RED DATA BOOK -- Vol. 3., Amphibia & Reptilia	916
MARINE TURTLES -- Coordination of conservation work	7,379
British Pounds (Almost $200,000 !)	79,581

NATIONAL GEOGRAPHIC SOCIETY

The National Geographic Society recently listed (NGS Research Reports, 1971) some of its research grants for 1969 and 1970. Among them were the following.

WILLIAM G. REEDER (Univ. Wisconsin, Madison) to study the distribution, ecology, and behavior of Galapagos tortoises.

WAYNE F. FRAIR (Kings Coll., Briarcliff Manor, N.Y.) for a taxonomic study of the giant leatherback turtle in Surinam.

THOMAS W. SCHOENER (Harvard Univ.) for a continuing study of the Anolis lizards of the West Indies.

ROGER C. WOOD (MCZ, Harvard Univ.) in aid of research on the systematics, evolution, and ecology of the pleurodiran turtles in South America.

WILLIAM P. HALL (MCZ, Harvard Univ.) in support of a study of the biogeography of karyotype variation in the iguanid lizard Sceloporus grammicus.

THE SOCIETY OF THE SIGMA XI

Sigma Xi makes a number of grants to promising scientists at critical points in their research careers. The following awards were selected from the 1970 and 1971 lists (AMER SCI 59). These are continued from HERPETOL REV 3(6): 116.

James F. Jackson, University of Florida. Perch niche size and variability of locomotor structures in *Anolis* (Iguanidae: Squamata). $200.

Robert O. Kelley, University of New Mexico. Localization of intracellular antigens in presumptive neural ectoderm of the South African frog *Xenopus laevis*. $200.

Chaim N. Kropach, City University of New York. The ecology and population structure of the sea snake *Pelamis platurus* in the Gulf of Panama. $200.

Ronald A. Nussbaum, Oregon State University. Evolution and systematics of the salamander genus *Dicamptodon*. $125.

Stephen R. Parcher, Oildale, California. (1) Search for marked chameleons. (2) Ecology and behavior of *Chamaeleo lateralis*. $300.

Elizabeth K. Perryman, University of Arizona. Electron microscopic study of control of pars intermedia of *Rana pipiens*. $400. RESA Award.

Marilyn L. Riese, Yeshiva University, New York, New York. Spreading depression and length of memory in frogs. $100.

[To be continued.]

CATALOGUE OF

AMERICAN AMPHIBIANS AND REPTILES

The CATALOGUE will have published 125 accounts by the time this issue of HR appears. Those that were included in 1971 subscriptions were:

101. CRYPTOBRANCHUS, C. ALLEGANIENSIS, by Harold A. Dundee.
102. PLETHODON ELONGATUS, by E. D. Brodie & R. M. Storm.
103. PLETHODON STORMI, by E. D. Brodie.
104. LEPTODACTYLUS LABIALIS, by W. R. Heyer.
105. RANA CASCADAE, by R. Altig & P. C. Dumas.
106. CHRYSEMYS PICTA, by C. H. Ernst.
107. DEIROCHELYS, D. RETICULARIA, by G. R. Zug & A. Schwartz.
108. ANOLIS DISTICHUS, by Albert Schwartz.
109. CNEMIDOPHORUS NEOMEXICANUS, by J. W. Wright.
110. OPHISAURUS
111. O. ATTENUATUS,
112. O. CERONI,
113. O. COMPRESSUS,
114. O. INCOMPTUS,
115. O. VENTRALIS, all by J. A. Holman.
116. EURYCEA AQUATICA, by Francis L. Rose.
117. RANA PALUSTRIS, by R. T. Schaaf & P. W. Smith.
118. PSEUDOBRANCHUS, P. STRIATUS, by B. S. Martof.
119. RANA PRETIOSA, by F. B. Turner & P. C. Dumas.
120. GASTROPHRYNE CAROLINENSIS,
121. G. ELEGANS,
122. G. OLIVACEA,
123. G. USTA, all by Craig E. Nelson.
124. CLEMMYS GUTTATA, by Carl H. Ernst.
125. CLEMMYS INSCULPTA, by C. H. Ernst.

We have some additional accounts in hand, and expect to publish another 25 accounts in 1972.

The emphasis to this date has been on species and genera that occur in the United States and Canada. We would like to complete this region before moving too far to the south. However, a number of forms still await authors.

The salamander accounts are the most nearly complete. Almost all of the genera and species have been either published or assigned. The remaining are as follows:

AMPHIUMA
- A. means
- A. tridactylum

Eurycea longicauda

PSEUDOTRITON
- P. montanus
- P. ruber

There are several frog accounts for which authors are still needed. These are:

ACRIS
- A. gryllus

BUFO
- B. americanus
- B. debilis
- B. marinus
- B. microscaphus
- B. punctatus
- B. quercicus
- B. retiformis
- B. speciosus
- B. terrestris

ELEUTHERODACTYLUS

HYLA
- H. arenicolor
- H. cadaverina
- H. chrysoscelis
- H. crucifer
- H. regilla
- H. squirella
- H. versicolor
- H. wrightorum (eximia?)

PSEUDACRIS
- P. brachyphona
- P. clarki
- P. nigrita
- P. ornata
- P. triseriata

RANA
- R. catesbeiana
- R. clamitans
- R. "pipiens"

SCAPHIOPUS
- S. bombifrons
- S. hammondii
- S. intermontanus

About sixty lizard accounts are still unassigned. These are:

ANOLIS
- A. carolinensis

CALLISAURUS
- C. draconoides

CNEMIDOPHORUS
- C. burti
- C. exsanguis
- C. flagellicaudus
- C. gularis
- C. inornatus
- C. scalaris
- C. sonorae
- C. tesselatus
- C. tigris

COPHOSAURUS
- C. texanus

CROTAPHYTUS
- C. collaris

DIPSOSAURUS
- D. dorsalis

EUMECES
- E. callicephalus
- E. obsoletus

GERRHONOTUS
- G. coeruleus
- G. multicarinatus

[TO BE CONTINUED]

Volunteers please write to the appropriate Section Editor, or directly to the CATALOGUE office (see third cover).

AN UNUSUAL ACCIDENT INVOLVING AN EASTERN KING SNAKE, Lampropeltis getulus getulus

John D. Groves and Estella M. Groves

On 2 September 1970 we collected a four foot kingsnake, Lampropeltis getulus getulus, from under a 6-foot square slab of concrete at a destroyed home, approximately 2 miles southeast of Massey, Kent County, Maryland. This snake had a zip-top ring (used on beverage cans) encircling its body about 6 inches from the head. The ring had cut into the snake to a depth of 1/4 inch,

FIGURE. Kingsnake with "zip-top" injury.

exposing parts of the esophagus and vertebrae (Fig. 1). The exposed damaged tissue was gangrenous.

The snake was taken to the Baltimore Zoo, where the ring and gangrenous tissue were removed. Nitrofurazone Ointment N.F. (Nitrofurazone 0.2% in a water soluble base of Polyethylene Glycols) was applied daily to prevent further bacterial infection. On 5 September the snake was sent to Dr. Mitchell Bush, Veterinarian and Assistant Professor of the Division of Laboratory Animal Medicine at Johns Hopkins University, School of Medicine, who sewed the wound with nylon sutures and removed the excessive hanging tissue and skin. The snake was then returned to the Baltimore Zoo, where daily application of Nitrofurazone was continued.

Recovery was quick and complete. The king snake was offered several juvenile Elaphe obsoleta on 9 September which were ingested immediately. Since 18 September 1970 this snake has eaten one to three mice per week. Shedding occurred weekly for a period of three months after the ring was removed. After this period shedding occurred on the average of twice each month.

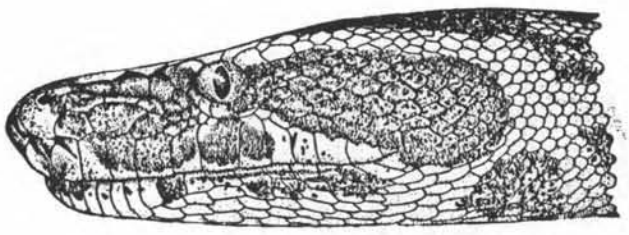
Reptile Department
BALTIMORE ZOO
Baltimore, MD 21217

REPORTS

The reports section of H R will publish notes of interest to herpetologists which ordinarily would not appear in scientific journals. These include information on specific items of morphology or physiology (e.g., karyotypes, temperature records), new geographic records or corrections, field-trip and life history records (e.g., seasonal appearance), and comments or corrections on previous papers published here or elsewhere. HERPETOLOGICAL REVIEW is not intended as an alternative to the ordinary publication of the results of scientific studies in established journals.

LOST MEMBERS

Publications of the SSAR or H L have been returned from the following individuals marked "Not Known" or "No Forwarding Address." We would appreciate any aid in obtaining current addresses.



EDD C. BAKER, Ft. Myers, FL 33901.
VICTOR L. CAMP, Carbondale, IL 62901.
CORBETT B. COBURN, JR., Macon, GA 31201.
ANDY COLLINS, Lexington, MA 02173.
GEORGIA M. GIBERSON, Long Beach, CA 90812.
MICHAEL KRULIK, Melrose Park, IL 60164.
JOSEPH R. LANNOM, JR., Mercury, NV 89106.
CHARLES F. MACGOWAN, Oakland, CA 94619.
DAVID J. MILLER, San Francisco, CA 96343.
JOHN MURPHY, Carbondale, IL 62901.

HERPETOLOGICAL HUSBANDRY

As indicated in the Editorial, we expect to initiate a regular column, edited by James Murphy of the Dallas Zoo, with the next issue.

Meanwhile, we are reprinting two articles on reptile care that were kindly sent to us by D. K. Blake, of the Rhodesian Department of National Parks and Wildlife Management. These are issued as mimeographed sheets as guidelines for reptile exhibitors.

These two articles should not be considered as our recommendations for care, but are presented for their interesting ideas and as an aid in establishing a format for this new section. -- HGD.

[From Witte, 1962.]

CAGE OR HOUSING MINIMUM SPECIFICATIONS FOR PYTHON: Python sebae (Gmelin)

Size

No cage for the confinement or housing of any python shall be less than 12 feet long, 6 feet wide and 6 feet high, providing that no python exceeding 11'6" total length shall be confined or housed therein. For the housing or confinement of any python exceeding 11'6" special application shall be made to the Department of National Parks and Wildlife Management for housing specifications.

At one end of the cage shall be a water trough which shall be finished to a smooth steel-floated cement surface. The trough, which shall extend over the width or depth of the cage, i.e. from front to back thereof, shall be two feet wide and shall be not less than one foot in depth. The trough is, with the exception of the upper three inches, to be below the floor level of the cage and the floor of the trough shall be sloped toward the rear of the cage so as to facilitate drainage and shall be fitted with a drain plug enabling the trough to be fully drained, the outflow of which shall be outside the cage. The filling pipe is to be situated at the front of the trough but shall be controlled from the rear of the cage.

Materials and Construction

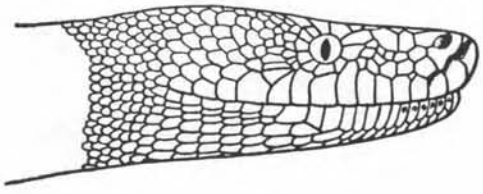
The cage to be built of brick or concrete and all internal walls to be smooth plastered with all internal corners and wall junctions rounded.

Viewing windows are to be fitted to the front of the cage only and shall be of plate glass puttied into a concrete or steel frame. NO WOOD IS TO BE USED. The use of "one way" glass is strongly recommended.

Access to the interior of the cage shall be from the rear only, and the door and frame shall be of metal construction and of the sliding type so constructed as to provide easy access to the interior of the cage for cleaning purposes.

All ventilation shall be at the rear of the cage, shall be of the standard airbrick wall type placed just below the ceiling of the cage and in number shall be not less than one for every two feet of cage length.

The cage shall be fitted with a ceiling of flat asbestos sheeting and there shall be an air space of not less than one foot between this ceiling and the roof over the cage, this gap to be closed at front and sides but left open at the rear. The roof shall be large enough so as to preclude all but early morning and late afternoon direct sunlight from striking the cage on any side.



A heating system shall be built into the floor or ceiling of the cage preferably of the thermostatically controlled convection type, so set as to maintain a constant interior ambient temperature within the cage of not less than 50 degrees F. Open bar heaters will not be permitted.

Floor Covering and Contents of Cage

Floor covering to be either coarse washed sand or small pebbles. A bed of clean straw is to be provided at the end of the cage opposite to the water trough. A large dead tree branch is to be placed in the cage upon which the reptile can climb and one or two large rocks should also be provided - these will provide a rough surface to assist the snake when skin sloughing takes place.

General distribution of Python sebae.

[From FitzSimons, 1962.]

Maintenance

Water trough to be drained, flushed and re-filled daily.

Cage to be checked at least once daily for faeces, shed skin, etc. and these are to be removed immediately together with any contaminated floor or bedding material.

All pythons in the cage shall be checked regularly for disease or damage.

The cage to be checked regularly for the presence of mites, if these are found the entire cage shall be cleaned out and fresh straw and dead tree branch provided. All old straw and tree branch to be immediately burnt.

Feeding

Live prey must not be left in the cage for periods longer than 24 hours and a food supply for such prey must be provided within the cage. Live prey should not be left in the cage during public viewing periods.

Dead prey may be left in the cage for periods not exceeding 12 hours provided that the condition of such prey was fresh when initially placed in the cage.

A written record of the feeding of pythons together with details of food taken, is to be kept. If it is found that any python has not fed over a continuous period of 90 days, this shall be reported immediately to the Department of National Parks and Wild Life Management and arrangements will be made for the release of the reptile.

Numbers

No more than three pythons shall be held at any one time in a cage constructed to the foregoing specification. All hatchlings or deaths shall be immediately reported to the Department in writing. No python may be sold, bartered, exchanged or released without the authority of the Director of National Parks and Wild Life Management.

Handling of python should be kept to a minimum and confined to that necessary for cage cleaning and the treatment of any injury or disease. No handling for display purposes is to be permitted.

The public are to be excluded from the rear of the cage at all times.

Appendix "B"

The following notice shall be prominently displayed in front of the cage where it is clearly visible:

PERMIT TO HOLD ROYAL GAME

Python are classified as Royal Game in terms of the Wild Life Conservation Act, 1960. These pythons are held in terms of Permit No. - - - - - - - - - - issued by the Department of National Parks and Wild Life Management.

Python are afforded the protection of Royal Game status because (a) they play an important part in the control of rodents; (b) are non-venomous and (c) could be in danger of mass slaughter for commercial gain leading to possible extinction of the species.

CONDITIONS FOR KEEPING CROCODILES

General

These conditions will apply to all crocodiles held in captivity, with the exception of crocodiles being reared for skin production or to crocodiles being held for scientific research. They will be applicable to crocodiles held by crocodile farms for display purposes.

Numbers and Size

The number of crocodiles which may be held in a pen at any one time will depend on their length. The categories given below show the number of crocodiles that may be held in each size group.

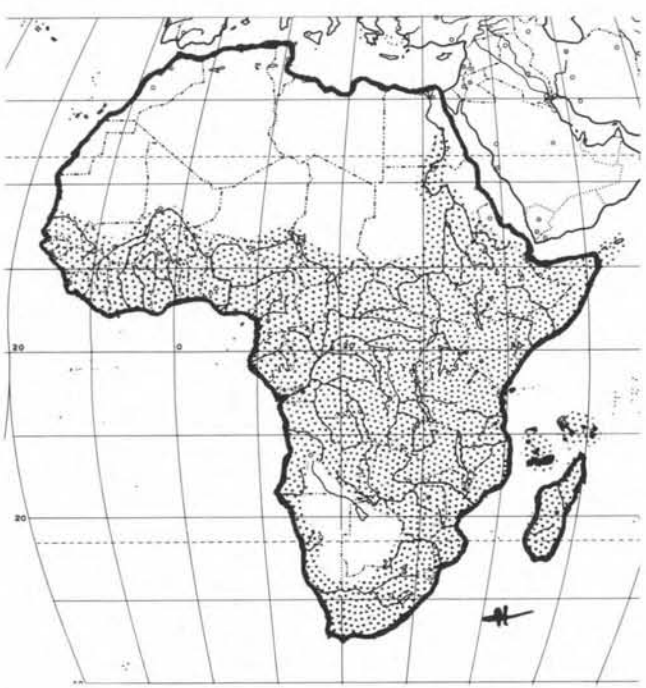
CATEGORY	SIZE	NUMBER
"A"	Under one metre in length	16
"B"	From one metre but under two metres	8
"C"	From two metres but under three metres	4
"D"	Three metres and over	2

Notwithstanding the abovementioned categories no crocodiles under three metres in length will be held in the same pen if the difference in length between such crocodiles is more than half a metre.

Pens

The pen may be constructed in any shape but will not be less than 100 square metres in area and no two sides may be less than four metres apart.

The walls of the pen will be constructed of brick or other suitable material and shall not be less than one metre in height, and the inner face will be smooth plastered. Where such pen is for public display, any wall accessible to the public will be topped by a fence of not less than 60 cms in height, having parallel strands not more than 10 cms apart and down strands or droppers not more than 50 cms apart.



Any door set into the wall will be solid and have no apertures therein. It will be fitted so as to open into the pen and will be fitted with an automatic closing device as well as having a suitable lock or padlock fitting. Any door or gate set on top of the wall in the fence will similarly be fitted with an automatic closing device and suitable lock or padlock fitting. Any steps leading up to the door or gate will be moveable and will be removed when not in use.

The pen will contain shelters or bushes large enough to provide shade for the crocodiles housed therein. It will also have cleared areas large enough for the crocodiles to be able to sun themselves. The area of the pen not taken up by the pond will be of earth or sand.

Ponds

The pen will contain a pond so constructed that the water surface is not less than five metres long and two metres in width. Water depth over 50% of the length of such pond shall not be less than one metre in depth.

The pond may be constructed of either concrete or earth but in both cases will be fitted with a drain and overflow drain. In either case the sides of the pond will slope so as to allow the crocodiles easy access to and from the pond.

General distribution of Crocodylus niloticus.

A concrete feeding dais will be constructed at one side of the pond with a channel from the pond leading around it. This dais will be constructed of concrete notwithstanding whether the pond is of concrete or earth construction.

Retreats

In pens containing concrete ponds or ponds into which the crocodiles cannot burrow into the walls, special retreats will be constructed.

The retreat will be dug into the floor of the pen in the area where flooding is unlikely and shall be covered with roofing over which at least 20 cms of sand or soil have been placed. The retreat will be large enough to contain all the crocodiles held in the pen and shall be large enough for the largest crocodile to turn around in.

Cleaning

The pen shall be cleaned daily of any faeces, dead meat etc. Where the pond is not adequately stocked with fish to keep it clean it will be drained weekly and cleaned out.

Handling

No handling of the crocodiles will be allowed for public display. Nor will the crocodiles be prodded or goaded into displaying or reacting for the public in any manner whatsoever. All handling will be restricted as much as possible and should be confined to that necessary for cleaning, reconstruction and the treatment of injury and disease.

Feeding

With the exception of fish, no live prey will be introduced into the pen. Feeding will be allowed during public visits but such feeding will not be done by the public.

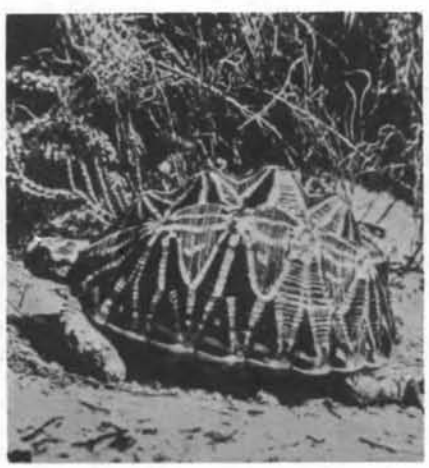
CAPE RESERVE FOR ONE OF WORLD'S RAREST TORTOISES

BY
R. RAU

The geometric tortoise, - listed as one of the most endangered tortoise species in the world - is to be protected in a special reserve in the Cape.

Among the many forms of African land tortoises the geometric group of southern Africa, is named because of the characteristic light and dark radiating colour pattern of the horny shields which cover the bony shell. Since there is a great deal of individual and local variation in shape, colour and pattern to be found in this group of tortoises, it is not surprising that various authors have recognised numerous species of geometric tortoises. However, in the latest revision of African tortoises (Loveridge and Williams 1957) many of them have been synonymised and at present only three species are recognised: *Testudo (Psammobates) geometrica, Testudo (Psammobates) oculifiera* and *Testudo (Psammobates) tentoria.*

Tentoria shows the greatest variation and has the largest area of distribution. *T. geometrica* is the rarest.



It was generally feared that this species, which was last reported on European pet markets before the first World War (Mertens 1962), had become extinct (Loveridge and Williams 1957). However "rediscovery" of *T. geometrica was* reported by Eglis (1965). It, together with the radiate tortoise of Madagascar, *T. radiata,* is recorded in the Red Data Book of the International Union for conservation of nature and Natural Resources (IUCN) in Switzerland, as the rarest and most endangered tortoise species on earth.

The East London Museum is, to my knowledge, the only institution which, in 1946 and 1947, obtained specimens of this species during the long period of uncertainty, from about 1910 to 1965 The South African Museum in Cape Town received one specimen in August, 1958, but this was only identified as *T. geometrica* in 1965.

Locality records for the geometric tortoise indicate that its distribution area was comparatively small and extended about 100 miles to the north and east of Cape Town, almost following the contour of the Rhenosterbushveld. The species exists in small numbers usually on small, isolated patches of uncultivated land.

While man was thought to be directly responsible for the rapid reduction in numbers of *T. geometrica* (utensil use by native tribes, local consumption as a delicacy and export to overseas pet markets), a different casual effect is involved. This animal, unlike other western Cape tortoises has become dependent on sour soil and its peculiar vegetation, typical of the area. Modern agricultural methods have made it possible to convert this useless veld into fertile farmland, thereby destroying the last remaining habitats of the geometric tortoise at an increasing rate each year.

The usually vast cultivated areas separating the island-like remnants of this habitat appear to be a barrier against migration from one patch to another. In addition to this, interbreeding may have an adverse effect on the population of such an "island". It should be noted, that hatchlings and juveniles are apparently absent from such islands, although their very effective camouflage makes it difficult to distinguish specimens from the criss-cross effect of light and shadow amongst bushes and especially sedges.

Female geometric tortoise, *Testudo (Psammobates) geometrica.* Carapace length 12,8 cm; carapace width 9,5 cm; shell height 7,8 cm.

Since man's agricultural activity has caused the rapid decline of this species, it has become man's moral duty to do everything possible to save this South African form of wild life from extinction. The need of protection was brought to the notice of the Department of Nature Conservation of the Cape some years ago and has recently been endorsed by IUCN and herpetologists.

A reserve of approximately six morgen of original suurveld (a locality which at present possesses the densest population of the geometric tortoise) has been approved by the Provincial Administration of the Cape. It is hoped that the fencing, for which suggestions have been submitted, will be started in the near future.

Although a somewhat bigger reserve would be desirable, the establishment of the proposed six morgen reserve, together with introduction of endangered specimens from a 20 mile radius of the reserve, should prove an important step in securing the future existence of an almost lost member of the world's reptile fauna.

The Department of Nature Conservation has recently included *T. geometrica* in a mammal survey questionnaire, which was sent to 22 000 farmers in the Cape Province. While many answers probably refer to other species, the positive replies from the former distribution area require further investigation.

As apparently in the case of the quagga, *Equus quagga quagga* Gmelin, which was exterminated during the second half of the last century, the possible extinction of the geometric tortoise must not go unnoticed because of a confusion in common names. *T. geometrica* is commonly called the suurpootjie (sometimes seerpoitjie and sierpoetjie) Suurpootjie has also been applied to the tent tortoise, *T. tentoria* and even the padloper, *Homopus aereolatus.*

Many questions concerning the distribution and ecology of this species could be efficiently answered, if funds were made available for full-time study.

SANTA CRUZ LONG-TOED SALAMANDER: SURVIVAL IN DOUBT

In recent years, the number of vertebrates threatened with extinction has markedly increased. Many of our North American amphibians and reptiles are declining in numbers as roads, suburbs, and industry engulf their habitats, and as man continues to poison, kill or collect these animals. One of the amphibians most seriously threatened with immediate extinction in North America is the Santa Cruz long-toed salamander, Ambystoma macrodactylum croceum. We describe here its present status.

A. m. croceum is listed in the U.S. Red Data Book and the I.U.C.N. Red Book as endangered. According to the U.S. Species Conservation Act of 1969 it may not be transported across state lines. The State of California has deemed it as both a fully protected and endangered vertebrate, whereby it is illegal to take, possess, harm, or sell Santa Cruz long-toed salamanders. Any person who violates the provisions of the California regulations may be subject to a maximum fine of $1,000 or imprisonment up to one year, or both. Clearly, we recognize A. m. croceum as an animal on the brink of extinction and have provided it with legal protection. However, populations are being eliminated because its limited habitat is being destroyed. There are only two known breeding populations of A. m. croceum. Both occur in temporary ponds and marshes in coastal Santa Cruz County, California. One site has already been altered by man, and the other is now threatened with obliteration.

Valencia Lagoon near Aptos is one site. It once was a large pond and marshy area, nestled between rolling, wooded hills. On January 12, 1970, road crews completed widening two lanes of Calif. Hwy. 1 which bordered the north end of the marsh. They constructed a new freeway and built a 75 foot wide storm channel south of the road. The drainage channel was designed to handle runoff from a "once in 100 years" type flood. This wiped out a good share of the marshy area, and drained all standing water. The freeway construction was nearly finished before the California Division of Highways learned they had destroyed the habitat for an endangered species. Conservationists bemoaned the devastation to this truly scenic spot. Dr. Robert C. Stebbins (pers. comm.) aptly said that the State Highway Division has until recently been largely unaware of the biological implications of their construction schemes. Further, he said that the fact that the disaster has befallen an obscure, little-known animal enhances the point that a creature need not be a whooping crane or as big as a redwood tree to warrant our concern.

Unlike past incidents, however, the Division of Highways desired to rectify the detrimental effects of the freeway construction. In February, 1970, Dr. Stebbins met at Valencia Lagoon with representatives of the Highway Division, U.S. Fish and Wildlife Service, California Fish and Game, and several private citizens, to determine what measures could be taken to restore the damaged site. Shortly thereafter, a blue print was drawn up for a 'salamander pond', the first such plan for a highway department, and construction was done during the summer of 1970. The new pond is 250 feet long by 50 feet wide, and 3 feet deep in the middle. Spike rushes (Heleocharis sp.), cattails (Typha sp.) and knotweed (Polygonum sp.) were planted along the edges of the water. The pond was open for salamanders in late 1970.

Despite the well-meaning measures taken by the Highway Division, there remains a serious threat to the survival of the Valencia Lagoon population. Construction of the storm channel left little surface cover, and kikyu grass (Pennisetum clandestinum) was planted to control erosion. It may be several years before the new pond returns to a heavily vegetated condition of native plants. Wooded slopes southwest of the pond serve as a summer refuge for the salamanders. Several houses and a dirt road are located here, and further development in the woods could destroy ground cover

essential to the survival of the adults.

The adults could not breed during the winter or spring of 1970 due to the lack of standing water. In April, 1971, one of us (Bury) checked the man-made pond and no salamanders or larvae were observed. Adults are presumed to be long lived and, perhaps, they will eventually return to the man-made pond. However, at this time we have no assurance the salamanders will continue as a viable population at Valencia Lagoon.

The second locality is 1/2 mile NW of Ellicott Railroad Station (4 miles west of Watsonville). The salamanders breed in an oval temporary pond which fills with water during winter and spring rains. The pond is variable in area, but is usually about 150 feet long and 120 feet wide at its greatest extent. Spike rush is a dominant plant but knotweed is also common. A dense thicket of willows (Salix sp.) and blackberry vines (Rubus sp.) cover an area about 840 square yards in size on the southeast side. Oak woodland occurs about 1/8 mile northeast of the pond. The area is now a cow pasture. A trailer park borders the site to the south, and roads or country homes surround the other sides. There are plans to build a trailer court for mobile homes at the Ellicott locality. Construction is imminent, and may start in early 1972. A special permit from the county Board of Supervisors was obtained to build the trailer park in this residential zone (country style homes). The trailer court, however, was recently denied a renewal of the building permit. At this time, they are trying to secure the permit and, apparently, will demand a sizable settlement from Santa Cruz County if they do not receive authorization to build at the Ellicott site. Most importantly, there is a temporary delay in the proposed destruction of the salamander pond. We recently brought the plight of the salamander to the attention of the Nature Conservancy and the Sierra Club, as well as state and federal agencies. Their responses and actions in the next few months may decide the fate of the Santa Cruz long-toed salamander.

The pond and willow thicket at the Ellicott site need to be acquired in order to save the habitat for the salamander population. However, this will be extremely difficult since the assessed land value is $5,000 per acre and, presumably, a 34 acre parcel must be purchased in one transaction. Further, the oak woodland habitat northeast of the pond is thought to be important refuge for transformed animals, and in the future this area could be razed for home construction.

If the Ellicott site can not be protected, adults and larvae could be transplanted to other ponds in the region in hopes of establishing a breeding population. However, moving salamanders to alternate sites is undesirable since there is no guarantee the transplantation will be successful.

There have been rumors of another locality with A. m. croceum in the Watsonville area, but we have no verification of this population. The entire region is being rapidly urbanized and suitable sites for the salamander are disappearing at a fast pace. A thorough search for the salamander is desperately needed in hopes of finding new populations and locating possible sites for transfer of some of the Ellicott salamanders if that site is to be destroyed. However, several workers have explored the Watsonville-Santa Cruz region in the past without uncovering the salamander, and the chances of finding new populations seem remote.

Continued surveillance of the Valencia Lagoon population is needed and, hopefully, the adults will return to breed in the man-made pond. The battle to save the Ellicott Station locality is starting. Without immediate action to save these areas, the continued survival of the Santa Cruz long-toed salamander is indeed questionable.

Acknowledgements. We thank Dr. Robert C. Stebbins for his review of this paper, and for his permission to use his files and information on the salamander.

ADDENDUM

On November 30, 1971, the Santa Cruz County Board of Supervisors voted 5 to 0 to deny rezoning of the Ellicott site from its present agricultural use to that of a proposed mobile home park.

A short-lived but intense campaign by a coalition of conservation groups and governmental agencies helped obtain the ruling. Testimony against rezoning was presented by representatives of the Sierra

The Salamander Wins Out over A Trailer Park

SANTA CRUZ, Calif. (AP) — Students, ecologists, and government officials have rallied to save the last breeding pond of the rare Santa Cruz long-toed salamander.

An overflow crowd of 120 persons heard the county Board of Supervisors vote 5 to 0 against a rezoning that would have allowed a developer to drain the pond eight miles south of here for a mobile home park.

Speakers argued that the proposed development would doom the rare amphibian, an eight-in-long, lizard-like creature, to extinction. Environmentalists presented petitions they said bore 850 signatures opposing the rezoning.

Stephen B. Ruth, a University of California at Berkeley zoology researcher, said the salamander has for 10,000 years laid eggs only at two small ponds near Santa Cruz, and one was drained in 1969 for a freeway extension.

Club, Nature Conservancy, Herpetologists' League, members of the Conservation Committee (Amer. Soc. Ichthyol. Herpetol.), California Office of the Attorney General, California Department of Fish and Game, U.S. Bureau of Sport Fisheries and Wildlife, Museum of Vertebrate Zoology, Cabrillo College, local youth groups, and free-lance conservationists. A deluge of mail expressing concern about the salamander was received by the Board of Supervisors, including a letter from the Assistant Secretary of the Interior.

Efforts are being made to protect the salamander habitat. Grazing of livestock previously denuded almost all vegetation at the site; these animals have been removed. Further, cover will be moved into the area to provide refuge for adult and transforming salamanders. A nearby well will be used to provide water for the pond since it has not filled sufficiently in recent years. Students at the Museum of Vertebrate Zoology are determining the extent of the terrestrial habitat used by adults.

However, the battle is not won. Negotiations are underway to purchase the land from the owners. Money is urgently needed to buy the pond and willow grove at Ellicott. Assistance in this project is being offered by several groups. The Santa Cruz County Board of Supervisors requested that the Secretary of the Interior take immediate steps to commit funds for acquisition of the property for a wildlife preserve. California Fish and Game is recommending to the State Assembly that funds be allotted for the purchase of part of the lands at Ellicott and for restoration of the habitat at Valencia Lagoon. The Santa Cruz County chapter of the Sierra Club will aid in a fund raising campaign to help in the land purchase. It will undoubtedly take a combined effort by these organizations and other groups to acquire a substantial area for the salamanders.

Letters of support and money are needed if this endangered salamander and its associated biota are to survive. Two options are available for contributions:

NATURE CONSERVANCY c/o SALAMANDER FUND, 215 Market Street, San Francisco, California 94105. This organization is non-profit and tax exempt; contributions are tax deductible. Their efforts have saved many natural areas in the past. However, it must be clearly known that if negotiations between the Nature Conservancy and the land owners should fall through then contributions to the salamander fund will be used for other projects.

SAVE THE SALAMANDER, Acct. No. 053 301 8511, Wells Fargo Bank. This is a separate fund established exclusively for the salamander. It was formed by conservationists in the Santa Cruz area in order to raise money locally, but will gladly serve as a depository for contributions from other areas. They have applied for incorporation as a non-profit organization, and tax exempt status is pending approval. Checks to this fund can be sent to any branch of the Wells Fargo Bank; be sure to show the account number. Or, checks can be sent to Wells Fargo Bank, Capitola, California 95010.

Also, letters to governmental agencies are needed. We urge you to express your opinions and interest to Roger C. B. Morton, Secretary, U. S. Department of the Interior, and Senator Alan Cranston, Senate Office Building, Washington, D.C. 20510, and to G. Ray Arnett, Director, Calif. Dept. Fish and Game, 1416 Ninth St., Sacramento, Calif. 95814.

[From Stebbins, 1951.]

GEOGRAPHIC DISTRIBUTION

HERPETOLOGICAL REVIEW will publish brief notices of new geographic records, in order to make these available to workers in published form. The STANDARD FORMAT for these records is:

SCIENTIFIC NAME. Locality /air-line distance and direction from a town/; Date; Collector. Identified or verified by. Place of deposition and catalogue number. Comments. SUBMITTED BY, and address.

Please submit new locality records to: GEORGE R. ZUG, Division of Reptiles & Amphibians, National Museum of Natural History, Washington, DC 20560.

NEW RECORDS

AMBYSTOMA TREMBLAYI. U.S.A., Wisconsin, Price Co., 13.5 miles ENE of Philips at abandoned CCC camp site on Elk River (T38N, R3E NE 1/4 Sec. 30); 30 April 1971; J. L. Briggs, G. Nelson. Personal collection #449, Milwaukee Public Museum #MPM-3468. Second record for the state of Wisconsin 72 miles southeast of the earlier Washburn record. No erythrocytes were examined before death of this female. Total length is 140 mm; Snout-vent is 70 mm, internarial distance is 4.7 mm. Submitted by J. L. BRIGGS, Department of Biology, University of Wisconsin-Whitewater, Whitewater, WI 53190.

CLEMMYS MUHLENBERGI. U.S.A., Pennsylvania, Northampton, Cherryville; 22 August 1935; Mary Kapenhaver. H. A. Dundee. Tulane University #158. First record for county. Submitted by J. L. BEHLER, Department of Herpetology, New York Zoological Park, Bronx, NY 10460.

HEMIDACTYLUS GARNOTII. U.S.A., Florida, Lee Co., Sanibel Island; 8 Dec. 1971; M. Graham Netting. C. J. McCoy. Carnegie Museum 55585 (3 specimens). First record for west coast of Florida, other localities in south Miami and Everglades National Park (King and Krakauer, 1966, Quart. J. Fla. Acad. Sci. 29(2): 145; Kluge and Eckardt, 1969, Copeia (4): 659). Submitted by C. J. McCOY, Carnegie Museum, Pittsburgh, PA 15213.

CORRECTION OF DISTRIBUTIONAL RECORDS FOR *GRAPTEMYS BARBOURI* AND *GRAPTEMYS PULCHRA*

James L. Dobie

Graptemys barbouri is apparently endemic to the Apalachicola River System. The sole indication to the contrary is a specimen at Tulane University (TU 13471) reportedly collected in the Escambia River (Cagle, 1952), whose outflow is approximately 150 miles west-northwest of that of the Apalachicola River. It is doubtful that this specimen bears the correct locality datum. Extensive collecting in the Escambia River System by Robert Mount of Auburn University and his field crews has yielded no *G. barbouri*. Neither have there been any *G. barbouri* collected in the Choctawhatchee River System or the Yellow River, both of which are east of the Escambia River System. *Graptemys pulchra*, however, is common in the Escambia River and also occurs in the Yellow River. Apparently, there are no *Graptemys* in the Choctawhatchee River System.

The original entry for TU 13471 in the Tulane University catalog, according to curator, Harold Dundee, was "*G. pulchra*," but someone marked through this and entered "*G. barbouri*." Specimen numbers TU 13464-89 were not entered in Cagle's field book. Presumably the animals were not catalogued in the field; TU 13463 was the last field book entry and was listed as *G. pulchra* from the Escambia River. Moreover, TU 15222.5, one of a series of skulls (TU 15222.1-15222.12) obtained from specimens reportedly collected in the Chipola River, is *G. pulchra*. The remainder are *G. barbouri*. *Graptemys pulchra* has not been reported from the Apalachicola River System and apparently does not occur there. It is logical to suspect that specimen TU 15222.5 is actually the one to which the Escambia River datum in question applies, and that TU 13471 belongs with the Chipola River series of *G. barbouri*. The Chipola series was collected on 12-14 July, 1950 and the Escambia series on 15-16 July, 1950; thus, an accidental exchange of the two specimens in question could have occurred easily.

Drs. George H. Blake, Jr., M. Keith Causey and Costas A. Kouskolekas kindly reviewed this manuscript. I thank Dr. Harold Dundee for the loan of specimens and for graciously checking on entries in the Tulane Catalog and in Cagle's field book.

AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS

The ASIH is the oldest and the largest of the international societies that have a major interest in herpetology. The object of the society "shall be to advance the science of the study of fishes, amphibians, and reptiles." Membership is open to "persons interested in the object of the society." The society had about 2,000 members in 1971, of whom perhaps 60 per cent have an interest in herpetology.

The officers of the society are elected at the annual meeting by the members present. However, the main business of the society is conducted by a Board of Governors which has a membership of 70 to 80 (50 Board-elected members, plus past presidents and current officers).

Joseph R. Bailey (Duke Univ.) is the President in 1972; Richard Highton (Univ. Maryland) is Secretary. The 1972 annual meeting will be held in Boston, 18-23 June. Attendance at the annual meetings is variable, but appears to be growing steadily, as shown by the following list.

1964	Morehead City, N.C.	218
1965	Lawrence, Kansas	264
1966	Miami, Florida	324
1967	San Francisco, Ca.	369
1968	Ann Arbor, Michigan	357
1969	New York, N.Y.	339
1970	New Orleans, La.	440
1971	Los Angeles, Ca.	423

The single publication of the society is the journal COPEIA (named for Edward Drinker Cope), which was founded in 1913 by John T. Nichols, and which has been published as a quarterly since 1930. It contained 806 pages in 1971, which were about equally divided between ichthyology and herpetology. About 1,000 institutions subscribe to the journal.

Annual dues, and subscriptions to COPEIA are as follows:

Foreign & Student Members	$ 8.00
Regular Members	10.00
Sustaining Members	25.00
INSTITUTIONAL SUBSCRIPTION	15.00

To join the society, or to obtain further information, write:

ASIH Business Office
Division of Reptiles-HR

HERPETOLOGISTS' LEAGUE

All persons interested in herpetology are eligible for membership.

Members receive HERPETOLOGICA (4 issues/year) and HERPETOLOGICAL REVIEW (6 issues/year). They may submit manuscripts for publication in both these journals, and may present papers at the League's Annual Meeting.

HERPETOLOGICA has been published regularly since 1936. All back issues are available.

Member..... $8.00

Fellow (elected).....$10.00

INSTITUTIONAL SUBSCRIPTION to HERPETOLOGICA.....$15.00

Write: HOBART E. LANDRETH
Secretary-Treasurer, H L
R. R. #1, Box 478
Oklahoma City, OK 73111

ADVICE TO AUTHORS

HERPETOLOGICAL REVIEW publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals. Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome.

FORMAT. Manuscripts should be type-written on white bond paper, one side only. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and the animal group(s) included. Use standard abbreviations for journals.

The 1971 YEARBOOK OF HERPETOLOGY (published by HISS) contains a list of American Standard abbreviations for some 2,500 journals. Other publications that will be of assistance in the preparation of manuscripts are:

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES (see information on this page).

Common names for North American amphibians and reptiles (COPEIA 1956(3): 172-185).

SCIENTIFIC WRITING FOR GRADUATE STUDENTS, by F. Peter Woodford (Rockefeller Univ. Press, New York, NY 10021). $5.75.

STYLE MANUAL FOR BIOLOGICAL JOURNALS (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, DC 20016). $3.00.

A publication that will be found helpful in planning and producing adequate illustrations is:

A HANDBOOK OF BIOLOGICAL ILLUSTRATION, by Frances W. Zweifel (University of Chicago Press, 58th Street at Ellis Avenue, Chicago, IL 60637).

Line-cuts are photo-offset directly with the text, and should have widths of 4 1/4 inches (one column) or 9 1/4 inches (two columns). Each line of illustration equals six lines of text (full page copy length is 12 3/4 inches). Line cuts are reduced about 25 per cent in processing.

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

PAGE CHARGES AND REPRINTS

Authors of articles or reports submitted to H R are asked to contribute toward their publication costs to the extent of $20 per page. This payment is not a prerequisite to publication. However, paid articles receive priority and are likely to appear earlier than others.

Page-charge payments entitle the author to 100 reprints (or tear-sheets) without additional charge. /Additional reprints may be purchased at $5/page/per 100 copies./

Cost-sharing of this kind allows additional publication without increasing H R's cost to Society members and subscribers. It is, thus, a method of holding dues and subscription rates at their present levels.

CHANGE OF ADDRESS

THE NEWSLETTER ON AMPHIBIANS AND REPTILES...
AND THE PEOPLE WHO STUDY THEM

VOLUME 3, NUMBER 6
DECEMBER 1971

S S A R

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

The SSAR encourages the acquisition of knowledge on amphibians and reptiles, and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communications between amateur and professional workers.

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society; they receive the JOURNAL OF HERPETOLOGY, HERPETOLOGICAL REVIEW, and issues of the Facsimile Reprint Series. They also receive reductions on the price of other Society publications. See the last page of this issue for information on membership and subscriptions.

HERPETOLOGISTS' LEAGUE

The Herpetologists' League is an international organization established by Major Chapman Grant in 1936. It is dedicated to furthering knowledge of the biology of amphibians and reptiles.

In 1970 it had 940 members and fellows, 24 life members, 10 honorary members, and 400 institutional subscriptions to its journal, HERPETOLOGICA.

All persons interested in herpetology are eligible for membership. Members receive HERPETOLOGICA (and now HERPETOLOGICAL REVIEW), to which they can submit manuscripts for publication. They may also present papers at the Annual Meeting.

See the last page of this issue for information on membership and subscriptions.

LETTERS TO THE EDITOR

HOW COLD ARE COLD SNAKES? COMMENTS ON THE RELIABILITY OF LOW TEMPERATURE RECORDS

F.Harvey Pough & Margaret B.Pough

Hundreds of herpetologists have recorded activity temperatures of reptiles and the criteria for significant measurements have been discussed at some length (Cowles and Bogert 1944, Heath 1964). Encounters with reptiles in unusually cold situations are chance events and there are far fewer measurements at the low end of the temperature range. Unfortunately, most existing measurements are of doubtful value because rigorous standards have not been applied to them.

Parks (1969) reported an instance of a bull snake (Pituophis catenifer) active at "near-freezing" temperatures. The snake in question was crawling along a road. The snake's body temperature was not measured, but was assumed to be low because the air temperature 1 inch above the road was 4 degrees C. We doubt that this line of reasoning is reliable as a general rule. The following example illustrates our point.

At 1600 hr on 27 February 1971 we found a garter snake (Thamnophis s. sirtalis) resting on a snowbank in a field of nearly unbroken crusted snow. The snake (an adult female, snout-vent length 59.5 cm, weight 107 gm) was about 1 m from a flat rock 20 cm in diameter. It was crawling uphill toward a loose rock wall surrounding a spring. The flat rock and rocks around the spring were the only snow-free areas within a radius of 50 m. The snake was capable of slow coordinated movements and flicked its tongue repeatedly. When approached it inflated its lungs but did not hiss, coil, or strike. The following temperatures were measured at the site of capture: snake cloacal temperature 4.0, snow surface 1.0, air 2 cm above the snow 1.0, surface of flat rock 5.0, black bulb thermometer on rock 9.0, air 1 m above the ground 13.5 degrees C. In an area clear of snow 50 m from the site of capture the temperature of grassy soil in the sun was 6.0 and bare soil was 7.0 degrees C.

We suspect that the snake had been sunning itself on the flat rock and in this position it had probably been able to attain a body temperature close to the 9 degree reading of the black bulb thermometer. The snake's body temperature is probably not particularly significant; if we had found it a few minutes earlier it would have been warmer, a few minutes later it would have been colder.

Air temperatures 30 cm inside the rock wall surrounding the spring (from which the snake had almost certainly emerged) ranged from 1.2 in wet areas to 4.6 degrees C in dry spots. These temperatures were probably relatively stable throughout the day and suggest that the snake had initiated activity at a body temperature in this range. Not knowing when or why the snake emerged it is impossible to say what outside temperature might have attracted it. If it had emerged earlier in the afternoon when the solar flux was greater it could probably have attained a higher body temperature by basking than the 9 degrees measured at 1600 hr. Honeybees had been flying in midafternoon, but by 1600 hr they were beginning to drop to the ground, apparently too chilled to fly.

We think that the difficulty of interpreting the significance of even these unusually detailed temperature measurements illustrates the caution that must be applied to observations of reptiles in cold situations. The problem has two facets: In the first place reptiles have remarkable ability to raise body temperature above ambient by absorbing solar energy. Pearson's (1954) report that Liolaemus in the Andes Mountains may have body temperatures 30 degrees C above air temperatures is a striking example. In the case cited here the garter snake's body temperature was well above the level that could be estimated from the substrate and air temperatures. Measurements of body temperature are thus absolutely essential in such reports. Secondly, even when the snake's body temperature is measured there is no assurance that the measurement has any ecological significance. All we can say from our measurement is that at a temperature of 4 degrees a garter snake is capable of coordinated activity. Interesting, perhaps, but we could have discovered the same thing more easily by putting a snake in a refrigerator. Ideally one would like continuous observation of the snake's activities with a simultaneous temperature record. This is unattainable in most cases. When only isolated temperature measurements are possible, we suggest that there are three points at which the snake's temperature is ecologically significant: when it initiates activity, the highest temperature it can attain by basking, and when it begins to retreat. Isolated temperatures recorded at other stages are of very little value.

THE PHILADELPHIA MEETING

of the HERPETOLOGISTS' LEAGUE

and the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

28 - 30 DECEMBER 1971

10:00 AM TUESDAY, DECEMBER 28, 1971

MEETING WITH THE EAST COAST HERPETOLOGICAL SOCIETIES AT THE REPTILE HOUSE OF THE PHILADELPHIA ZOO (34th St. & Girard Ave.)

CONTRIBUTED PAPERS

Arranged by T. Paul Maslin
Curator of the Zoological Collections
University of Colorado Museum
Boulder, CO 80302

TUESDAY, DECEMBER 28, 1971 Benjamin Franklin Hotel, Valley Forge Room

1:30 PM Chairman: MALVIN L. SKAROFF, President Philadelphia Herpetological Society.

Display-action-patterns in the Iguanid Genus Sceloporus. CHARLES C. CARPENTER (Department of Zoology, University of Oklahoma, Norman, OK 73069).

Orientation of the Spadefoot Toad, Scaphiopus bombifrons. HOBART F. LANDRETH and MIKE T. CHRISTENSEN (Department of Zoology, University of Oklahoma, Norman, OK 73069).

Social Behavior of Some Australian Geckos. BAYARD H. BRATTSTROM (Department of Biology, California State College, Fullerton, CA 92631).

Ecotypic Selection in Southeastern Salamanders. GEORGE W. FOLKERTS (Department of Zoology-Entomology, Auburn University, Auburn, AL 36830).

Sound Production and Hearing in the Rattlesnake. JOSEPH M. PYLKA, JAMES A. SIMMONS and GLEN E. WEVER (Auditory Research Laboratories, Princeton University, Princeton, NJ 08540).

Polarized Light: Detection Via Extraoptic Receptor and Its Use By Orienting Salamanders. KRAIG ADLER and DOUGLAS H. TAYLOR (Department of Biology, University of Notre Dame, Notre Dame, IN 46556).

WEDNESDAY, DECEMBER 29, 1971 Benjamin Franklin Hotel, Ballroom Foyer

9:00 AM Chairman: JAMES A. PETERS, (Division of Reptiles and Amphibians, U.S. Natural History Museum, Washington, DC 20560).

Hematological and Serological Studies on Sea Turtles. WAYNE FRAIR (The King's College, Briarcliff Manor, NY 10510).

Pesticide Residues in Snakes. DONALD F. CLARK, Jr., ROBERT R. FLEET and FREDERICK W. PLAPP (Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, TX 77843).

Effect of Bile Pigments on Critical Thermal Maxima of Frogs. DUVAL A. JONES (Department of Biological Sciences, Carnegie-Mellon University, Pittsburgh, PA 15213).

The Physiological Responses of Western Diamondback Rattlesnakes to low Temperatures. HOBART F. LANDRETH (Department of Zoology, University of Oklahoma, Norman, OK 73111).

Biochemical Divergence in Isolated Populations of the Tree Lizard, Urosaurus ornatus. C. O. MCKINNEY, F. R. KAY, R. A. ANDERSON and W. L. ROUECHE (Department of Biology, University of Dayton, Dayton, OH 45409).

Reproduction in the Southern Alligator Lizard Gerrhonotus multicarinatus. STEPHEN R. GOLDBERG (Department of Biology, Whittier College, Whittier, CA 90608).

Behavioral Studies on the Green Turtle, Chelonia mydas, in the Sea. JULIE BOOTH and JAMES A. PETERS (National Museum of Natural History, Division of Reptiles and Amphibians, Washington, DC 20560).

A New Crotalus lepidus from West Central Mexico. JAMES R. DIXON and WILMER W. TANNER (Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, TX 77843. Department of Zoology, Brigham Young University, Provo, UT 84601).

11:00 AM WILMER W. TANNER, President, Herpetologists' League (Department of Zoology, Brigham Young University, Provo, UT 84601).

BUSINESS MEETING.

WEDNESDAY, DECEMBER 29, 1971.
Benjamin Franklin Hotel, Ballroom Foyer

1:30 PM Chairman: T. PAUL MASLIN (President-Elect, Herpetologists' League)

Functional Aspects of Tongue Projection Mechanisms in Plethodont Salamanders. DAVID B. WAKE (Museum of Vertebrate Zoology, University of California, Berkeley, CA 90007).

Comments on the Distribution of Desmognathus fuscus in the Southern Appalachian Mountains. STEPHEN G. TILLEY (Department of Biological Sciences, Smith College, Northampton, MA 01096).

Characteristics of F1 Hybrid Tadpoles Between Six Species of Hyla. JON R. FORTMAN and RONALD ALTIG (Department of Zoology, Mississippi State University, State College, MS 39762).

Inverse Correlation of Rana sylvatica and Ambystoma opacum Larval Survivorship. C. ROBERT SHOOP and THOMAS L. DOTY (Department of Zoology and Institute of Environmental Biology, University of Rhode Island, Kingston, RI 02881).

Shift in Perch Height Characteristics of Anolis opalinus (Sauria, Iguanidae) Due to Congeneric Competition. THOMAS A. JENSSEN (Department of Biology, Virginia Polytechnic Institute and State University, Blacksburg, VA 24061).

Bioenergetics of the Broad-headed Skink (Eumeces laticeps). EDWIN D. PENTECOST (Department of Zoology, University of Illinois, Urbana, IL 61801).

Biophysical Ecology of Large Reptiles: a Mathematical Model for Heat Flow Within the Body. JAMES A. SPOTILA and PAUL W. LOMMEN (Department of Zoology, University of Michigan, Ann Arbor, MI 48104).

Anoxic Tolerances of Five Species of Larval Amphibians. DIANA L. WEIGMANN and RONALD ALTIG (Department of Zoology, Mississippi State University, State College, MS 39762).

Annual Lipid Deposition-depletion Cycles in the Lizard Cnemidophorus tigris marmaratus (Sauria, Teiidae). FRED G. GAFFNEY and LLOYD E. FITZPATRICK (Department of Biological Sciences, North Texas State University, Denton, TX 76203).

Further Investigations on the Toxins of Taricha granulosa). EDMUND D. BRODIE, Jr. (Department of Zoology, Clemson University, Clemson, SC 29631).

An Extreme Degree of Transferrin and Albumen Polymorphism in a Population of the American Toad (Bufo americanus). SHELDON I. GUTTMAN and KENNETH G. WILSON (Department of Zoology, Miami University, Oxford, OH 45056).

THURSDAY, DECEMBER 30, 1971 Benjamin Franklin Hotel, Ballroom Foyer

9:00 AM Chairman: CLARENCE J. MCCOY (Chairman-Elect, SSAR)

Reproductive Variation Within a Single Subspecies of Painted Turtle Chrysemys picta belli Over a Large Geographic Area. JAMES C. CHRISTIANSEN and EDWARD O. MOLL (Department of Biology, Drake University, Des Moines, IA 50311).

Latitudinal Variation in Reproduction and Reproductive Cycles of the Painted Turtle, Chrysemys picta (Schneider). EDWARD O. MOLL (Department of Zoology, Eastern Illinois University, Charleston, IL 61420).

Repression of Egg-eating Behavior in Brooding Females of Desmognathus ochrophaeus. STEPHEN G. TILLEY and MARY G. AITAIO (Department of the Biological Sciences, Smith College, Northampton, MA 01060).

A Comparison of Incubation Periods of Turtles of the Western Great Lakes Region. MICHAEL A. EWERT (RR #2, Box #309, Bloomington, IN 47401).

Digestive Efficiency in the Herbivorous Lizard, Ctenosaurus pectinata. GAYLORD S. THROCKMORTON (Committee on Evolutionary Biology, University of Chicago, 5734 S. Ellis Ave., Chicago, IL 60637).

Bioenergetic Aspects of Herbivory in Lizards. F. HARVEY POUGH (Section of Ecology and Systematics, Langmuir Laboratory, Cornell University, Ithaca, NY 14850).

Ecological Energetics of Three Ectothermic Vertebrates. GARRY C. SMITH (Department of Biology, Furman University, Greenville, SC 29613).

The Saurian Renal Sexual Segment; a Functional Enigma -- Evidence for Sperm Sustenance. HECTOR S. CUELLAR, JAN J. ROTH, JAMES D. FAWCETT and RICHARD E. JONES (Department of Biology, University of Colorado, Boulder, CO 80302).

The Morphology of Reptilian Pancreatic Islets as Observed by Light and Electron Microscopy. WILLIAM A. RHOTEN (Department of Pathology, Washington University School of Medicine, 4550 Scott Ave., St. Louis, MO 63110).

Chromosomal Evolution of the Iguanid Lizard Genus Sceloporus. WILLIAM P. HALL III (Museum of Comparative Zoology, Harvard University, Cambridge, MA 02138).

Computer Cards for Indexing Reprints. ROBERT C. FEUER and JOAN F. FEUER (Philadelphia College of Pharmacy and Science, Philadelphia, PA).

ADLER, KRAIG and DOUGLAS H. TAYLOR (U. Notre Dame and Miami U.).

Polarized Light: Detection Via Extraoptic Receptor and Its Use By Orienting Salamanders.

Tiger salamanders (Ambystoma tigrinum) were trained to move along a specific axis in an indoor tank under a polarized light (produced by a polarizing filter, HN-38 Bausch & Lomb). Orientation tests were performed indoors in a small water-filled arena which was completely enclosed in opaque plastic. Animals were placed individually in the center of the arena beneath the polarized light source, then released and allowed to move to the edge of the arena where they were scored. Directional responses of salamanders in the arena were the same with respect to the plane of polarization as they had been in training. Rotation of the polarization filter by 90° produced corresponding changes in the direction of movement.

Orientation to the plane of polarization can be demonstrated in sighted and eyeless animals. However, if opaque plastic is inserted over the skull of blinded animals, movement is at random; oriented movement is restored in these animals, however, when clear plastic is substituted. These studies suggest that the critical receptor for polarized light is extraoptic. (Adler supported by NSF GB-30647 and NIH Biomedical Support Grant FR07033-05; Taylor by an NSF Postdoctoral Fellowship, GU-2058)

BOOTH, JULIE and JAMES A. PETERS (Nat. Mus. of Natur. Hist.). Behavioral Studies on the Green Turtle, Chelonia mydas, in the Sea.

Abstract not received.

BRATTSTROM, BAYARD H. (Calif. State Coll.). Social behavior of some Australian Geckos.

Abstract not received.

BRODIE, EDMUND D., JR. (Clemson Univ.). Further investigations on the toxins of Taricha granulosa.

The level of toxicity was found to be two to four times greater than previously published (Brodie: Copeia 1968: 307): the methods were those previously described. It was found that 0.0001 to 0.00005 cc of back skin of Taricha granulosa injected intraperitoneally killed 20g white mice. Ova and liver tissue were also tested; 0.0005 cc of ova and 0.01 cc of liver were sufficient to kill white mice. After subjecting the toxin mixture to 110° C for 8 hours the level of toxicity was reduced by 10 to 25 percent. Thirty-six feeding experiments with snakes indicated that occasional individuals of Thamnophis sirtalis are able to eat Taricha as previously reported; despite this all Thamnophis sirtalis died after being force-fed Taricha. Supported by NSF - Gb -2496 to the Highlands Biological Station.

CARPENTER, CHARLES C. (Univ. Oklahoma).
Display-action-patterns in the iguanid genus Sceloporus.

Aggressive displays are species-specific time-motion performances. The ritualized action, termed the display-action-pattern, can be depicted graphically. Other display characteristics include postural changes and proportional movements of different parts of the body. The large iguanid genus Sceloporus contains approximately 60 species and 130 described formsranging widely over North America south to Central America. 15 subgeneric groups have been proposed on the basis of scale topography. Data, obtained by single-frame analysis of motion pictures, indicate display-action-patter sequences vary in being determinate or indeterminate, in the amplitude and the length of movements and pauses between movements, and in repetition. This film presents the display-action-patterns of 40 species, and action shots of 21 of these species, demonstrating display characteristics to be considered relative to phylogenetic affinities, allopatry and sympatry, and ecology.

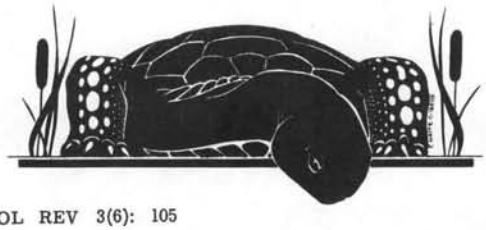
CHRISTIANSEN, JAMES L. (Drake U.) and EDWARD O. MOLL (Eastern Ill. U.)
Reproductive variation within a single subspecies of painted turtle Chrysemys picta belli over a large geographic area.

Reproductive cycles of painted turtles were studied in Wisconsin and New Mexico for several years. The annual period of locomotor activity is shorter in Wisconsin than in New Mexico and food consumption ends before locomotor activity. The testicular cycle begins in July with maximum testicular size attained in August in both localities. Testicular regression begins in September with minimum sizes attained in spring. Testicular regression is not as severe in Wisconsin as in New Mexico. In general follicular growth occurs from March through June and ovulation and oviposition from May through mid-July. A period of ovarian quiescence lasts from early July through August and follicular growth begins again in September. The cycles differ in that the Wisconsin cycle is compressed with the quiescent period about one month shorter than in New Mexico. The mean clutch size for turtles from Wisconsin and New Mexico is 9 and 10 respectively. Approximately half the painted turtles in both localities produce two clutches of eggs per year and about 14% of those from New Mexico produce three. The larger clutch size in Wisconsin at least compensates for the additional clutch in New Mexico and results in comparable reproductive potentials in the two localities.

CLARK, D. R., JR., R. R. FLEET, AND F. W. PLAPP (TEXAS A&M U.). Pesticide residues in snakes.

Between 8 April and 5 September 1971, field studies were made of the snake faunas of riparian habitats associated with the two major rivers of Brazos County, Texas. Analyses for pesticide residues were made on 35 specimens of 10 species. Heavy residues (up to 1009 ppm) of DDT and related compounds were found in fat bodies of snakes from the Brazos River flood plain where these materials are being or have been used in cotton production. Only small residues (up to 14.6 ppm) were found in specimens from the Navasota River which drains land used for grazing. At each locality, higher residues were found in species of high trophic level that live in or feed from the water, whereas lower residues occurred in species of lower trophic level or those that feed away from water. Utilizing the information theory index $H_s = -\sum_{i=1}^{s} p_i \log p_i$, species diversity for the area of high concentrations is 1.634, whereas this value is 1.924 for the area of low concentrations. In the area of high pesticide use, only one record (a shed skin) from a total of 71 was of an oviparous species. By contrast, 7 of 43 records from the area of low usage were of egg-layers. The difference between ratios is highly significant (Yates' corrected $\chi^2 = 6.940$; $.01 > P > .005$). The data suggest that certain snake species, particularly egg-layers, have been eliminated from the Brazos River area by pesticides.

CUELLAR, HECTOR S., JAN J. ROTH, JAMES D. FAWCETT AND RICHARD E. JONES (Univ. Coloraro). The Saurian Renal Sexual Segment; a Functional Enigma - Evidence for Sperm Sustenance.



The sexual segment of the kidney of male lizards and snakes hypertrophies during the breeding season and in most species returns to a quiescent state between breeding periods. Its function is unknown. This study was conducted to determine if macerations of kidney sexual segment enhanced duration of sperm motility. Sperm suspensions from the epididymis of breeding male Anolis carolinensis were cultured in the following: 1) buffered saline alone, 2) buffered saline plus macerations of either male kidney containing a hypertrophied sexual segment or 3) female kidney containing no sexual segment, 4) buffered saline plus male liver, and 5) buffered saline plus male skeletal muscle. Only male kidney tissue significantly increased ($< .05$) the per cent of motile sperm over that found in sperm cultured in saline. It is possible that secretions from the sexual segment of the male kidney activate or provide nutrients for sperm.

DIXON, JAMES R. and WILMER W. TANNER (Texas A&M U.). A new Crotalus lepidus from West Central Mexico.

Abstract not received.

EWERT, MICHAEL A. (Indiana U.). A comparison of incubation periods of turtles of the western Great Lakes region.

In order to bioassay developmental rate, eggs from nine species were housed with those from a single population of Chrysemys picta belli and incubated to hatching at 25° and 30°C. Eggs were also incubated at variable temperatures including samples placed in field plots. Results indicate that overall development (from laying to hatching) at 25° and 30°C is most rapid in Clemmys insculpta and Chrysemys picta. Development of Chelydra serpentina and Sternotherus odoratus is 85-90% as rapid as that of the C. p. belli controls at both 25° and 30°C. That of Trionyx spp. is also 85-90% as rapid at 30°C but only about 70% at 25°C. Relative incubation times at variable temperatures paralleled results at the cooler constant temperature (i.e. C. insculpta among the briefest; Trionyx among the longest). Temperature independent increases in developmental rate with increasing latitude are evidenced in C. picta and S. odoratus. These findings are discussed in terms of thermal ecology, nest site selection and nest failure of the various species.

FEUER, ROBERT C. (Philadelphia Coll. Pharmacy & Sci.) and JOAN F. FEUER (Cox Inst., Hosp. of Univ. of Pa.). Computer Cards for Indexing Reprints.

Computer cards allow reprints to be indexed inexpensively, no matter how the reprints are filed (i. e. by author, number, or subject). Cross-indexing is easy. Disadvantages include the need to prepare cards on a key-punch and the need to use a card sorter at least occasionally.

FOLKERTS, GEORGE W. (Auburn Univ.). Ecotypic variation in salamanders of the southeastern U.S.

In the southeastern U.S., several species of salamanders contain variant populations which seem to be the results of ecotypic selection. These demes occur in habitats significantly different from those "typically" occupied by the species involved. The adaptive significance of the unique features sometimes seems apparent, but in other cases is obscure. Evidence indicates that certain of these ecotypes may have evolved in comparatively short periods of time. Species in which such populations are thought to occur include Desmognathus fuscus, Desmognathus aeneus and Eurycea bislineata. These presumed ecotypes are the cause of considerable confusion because (1) some have been thought of as distinct species, (2) they may appear to form polytopic subspecies, (3) they may be thought of as ecophenotypes, (4) they are difficult to distinguish from relict phenotypes.

FORTMAN, JON R. and RONALD ALTIG (Miss. St. U.) Characteristics of F1 hybrid tadpoles between six species of Hyla.

Twelve hybrid crosses were made involving Hyla avivoca, H. chrysoscelis, H. femoralis, H. gratiosa, H. cinerea, and H. squirella. Iridophore and melanic pigment patterns, oral papillae and labial teeth characteristics, and body proportions of the hybrids were compared with the parent species. The distinctive iridophore patterns of H. avivoca and H. cinerea were seen in all hybrids involving those species, and the tail patterns of H. avivoca, H. femoralis, and H. gratiosa were evident in the respective crosses. A long posterior third row of labial teeth is apparently a dominant trait. The A-2 gap ratio was too variable to be of use.

Frair, Wayne
Hematological and Serological Studies on Sea Turtles.

Samples of blood have been taken by cardiac puncture from the sea turtles, *Caretta c. caretta, Chelonia m. mydas, Dermochelys coriacea, Eretmochelys i. imbricata, Lepidochelys kempi* and *Lepidochelys olivacea*. Hematocrit readings have varied greatly but ranged into the 40's which are values higher than found among other turtles. Erythrocytes have sizes between 19μ length by 11μ width and 25.7μ length by 16.7μ width. Electrophoresis of serum on cellulose acetate and immunological reactions using rabbit antiserum indicate a relatively close affinity among the marine chelonians.

Gaffney, Fred G. and Lloyd C. Fitzpatrick. (North Texas State University). Annual lipid deposition-depletion cycles in the lizard Cnemidophorus tigris marmoratus (Sauria, Teiidae).

Rates and energetics of lipid deposition-depletion in adult male and female Cnemidophorus tigris from El Paso Co., Texas were followed during August, 1970 to August, 1971. Quantitative lipid changes in fat bodies, carcasses, livers, and ova indicate that lipids are used for overwintering and reproduction. Fatty acids in pre- and post- "hibernation" lizards were analysed. Males and females enter "hibernation" (late August) with a greater quantity of total body lipids than is present at emergence (mid May). In females total body lipids are maximum prior to vitellogenesis and minimum immediately following oviposition.

GOLDBERG, STEPHEN R. (Whittier Coll.). Reproduction in the southern alligator lizard Gerrhonotus multicarinatus.

A population of Gerrhonotus multicarinatus webbi was studied in the Puente hills, north of Whittier, Los Angeles Co., Calif. Histological examinations indicate that testes contain sperm from late February through late May. Three occurrences of mating were noted in the field: 24 March, 8 April, 5 May. A gradual errosion of germinal epithelium occurs during May. Spermiogenesis ceases by the beginning of June at which time germinal epithelium consists of spermatogonia and Sertoli cells. This condition remains unchanged during July. A proliferation of spermatogonia in August indicates the start of the new testicular cycle. Recrudescence is completed during September. These changes are shown by increased testicular size and the presence of large numbers of primary spermatocytes. Yolk deposition commences in late March and may be completed by mid-May. The period of egg-laying encompasses June and the first half of July. The first hatchling was collected 19 August indicating approximately eleven weeks are needed for completion of development under natural conditions.

GUTTMAN, SHELDON I. and KENNETH G. WILSON (Miami Univ., Ohio). An extreme degree of transferrin and albumin polymorphism in a population of the American toad (Bufo americanus).

A population of Bufo americanus from southwestern Ohio exhibited an extreme degree of transferrin and albumin polymorphism. One hundred and seventy-two individuals were collected from this population and their plasma transferrin and albumin phenotypes were determined by vertical acrylamide gel electrophoresis. Thirteen transferrin alleles were present in 36 phenotypes and 11 albumin alleles were present in 29 phenotypes. An excess of homozygotes occurred at both protein loci. This represents the greatest degree of heterogeneity ever reported for a vertebrate population.

Hall, W.P. (MCZ, Harvard). Chromosome evolution or the iguanid genus Sceloporus.

My data from 42 of 61 Sceloporus species, plus abundant comparative data of my own and from published sources, show that the "ancestral" karyotype of Sceloporus is 2n=34 [12 metacentric macrochromosomes, 22 microchromosomes with male heteromorphic sex chromosomes]. Karyological and electrophoretic studies of cryptic species in grammicus suggest that fixation of Robertsonian mutations (centric fissions or fusions) between populations is probably closely involved in speciation. Three independent lineages of such chromosomal speciation are recognized in Sceloporus: 1) An ancient one giving rise to merriami [2n=46]. 2) An old one from jalapae [2n=34] to the aeneus group [2n=24]. 3) A comparatively recent one from the orcutti group [2n=34], involving all of Smith's large-sized, large-scaled branch, to end branches in: a) the horridus and malachiticus groups [2n=22 in all], b) the clarkii group []n=40], and c) the crevice using branch; asper plus torquatus, megalepidurus, and grammicus groups [2n=32♀, 31X_1X_2Y'o]. Survival of karyotypic intermediates allows these sequences to be reconstructed in detail. The most recent burst of chromosomal speciation, involving a minimum of 6 cryptic species in grammicus, shows 2 lineages; to 2n=34♀, and to 2n=46♀.

JENSSEN, THOMAS A. (Va. Poly. Inst. & St. Univ.). Shift in perch height characteristics of Anolis opalinus (Sauria, Iguanidae) due to congeneric competition.

A shift in perch "preference" was found in Anolis opalinus between two geographic localities on Jamaica. In Mandeville, near the island's center, A. opalinus characteristically perches low (1.37± S.E. 0.09 feet). In Kingston, 65 mi east of Mandeville, A. opalinus is much more variable in its perch characteristics and perches significantly higher than in Mandeville. From extensive observation it was established that Anolis l. lineatopus (present in Kingston, but not in Mandeville) is responsible for displacing A. opalinus into higher perch sites in the Kingston area. Anolis l. lineatopus also perches low (3.31 ±S.E. 0.19 feet) and forces A. opalinus up when the two species come into immediate contact.

JONES, DUVALL A. (Carnegie-Mellon Univ.). Effect of Bile Pigments on Critical Thermal Maxima of Frogs.

Biliverdin is known to accumulate in the tissues of dozens of species of tropical frogs. This chlorotic condition appears to be normal for the affected species and frequently makes its appearance during metamorphosis. The green pigmentation is not visible externally in many of these species, so that its selective advantage is not entirely a matter of protective coloration. Since a large proportion of chlorotic species is exposed to high temperatures, the relationship between bile pigment concentration and temperature has been studied. Groups of Wisconsin Rana pipiens acclimated to 5° C. were injected with solutions of biliverdin or bilirubin in phosphate buffer (100 mg bile pigment/kg wet weight of frog), and placed in a water bath at 25° C. with control frogs. Condition and behavior of the frogs was noted as temperature of the water bath was increased slowly. The critical thermal maximum was determined by noting the temperature at which each frog lost the ability to right itself. Average CTM's were: control group - 34.8° C.; bilirubin group - 36.7° C.; and biliverdin group - 36.3° C. The t-test indicated that each treated group was significantly different from the control group. Field studies have shown chlorotic species of frogs to have higher CTM's than some non-chlorotic species.

LANDRETH, HOBART F. (U. Oklahoma). The Physiological responses of western diamondback rattlesnakes to low temperature.

Abstract not received.

LANDRETH, HOBART F. and MIKE T. CHRISTENSEN (Univ. Okla.) Orientation of the Plains Spadefoot Toad, Scaphiopus bombifrons, to Solar Cues.

The ability of plains spadefoot toads, Scaphiopus bombifrons, to use solar cues in orientation and learning directional goals was analyzed. Orientational tests were conducted with animals moving toward breeding sites and taken from breeding aggregations. Toads used the sun to guide their migrations to breeding aggregations and used a y-axis mechanism relative to a shoreline while breeding.

Training tests revealed that these anurans learn directional goals rapidly when the sun was the only apparent cue. Collection data reveal that this species can migrate at least a mile to breeding sites and that they are often active several days prior to heavy rains in the spring.

McKinney, Charles O., F. R. Kay, R. A. Anderson, and W. L. Roueche, III. (Univ. of Dayton). Protein variation in isolated populations of the tree lizard, Urosaurus ornatus.

Ten isolated populations of the tree lizard, Urosaurus ornatus from southern New Mexico and western Texas, were examined to determine the effects of isolation on protein variation. Starch gel electrophoresis techniques were used to evaluate variation in proteins controlled by 13 loci. The isolated populations were found to exhibit patterns of variability indicating genetic drift as well as patterns indicating that selection may be very important.

MOLL, EDWARD O. (Eastern Ill. Univ.). Latitudinal variation in reproduction and reproductive cycles of the painted turtle, Chrysemys picta (Schneider).

Populations of Chrysemys picta from the Mississippi drainage were sampled throughout the period of activity at various latitudes from northern Wisconsin to mid-Louisiana. Gonads were removed and examined histologically. Data concerning timing of the reproductive cycle, size and age at sexual maturity, number of eggs per clutch and number of clutches per year were compared for each collection locality. Generally, turtles in northern populations mature later, at a larger size, lay more eggs per clutch and fewer clutches per year than southern populations. Events of gonadal cycles are more crowded together with shorter periods of quiescence between cycles in northern populations. The observed variation is not clinal and appears to be inherent rather than induced by the environment.

PENTECOST, EDWIN D. (Univ. of Illinois). Bioenergetics of the broad-headed skink (Eumeces laticeps).

Existence metabolism in caged animals was determined for adult Eumeces laticeps, acclimated at temperatures of 22, 28, and 34°C, as the difference between the caloric value of food ingested (I) and the excreta lost (E) while maintaining constant weight. An increase in temperature resulted in a linear increase in existence metabolism. A comparison of regression coefficients for existence metabolism between males (1.084 cal./°C) and females (1.600 cal/°C) showed the females to be more affected by an increase in temperature than were the males ($p<.05$). No significant difference was found in the utilization coefficients $(\frac{I-E}{I})$ at different temperatures. A comparison of standard metabolism between 22° and 34°C acclimation groups showed no significant difference at three experimental temperatures. The effect of increasing temperature on standard metabolism was the same for both males and females. Females were found to have a higher weight specific metabolic rate at all experimental temperatures correlated with their lighter weight.

POUGH, F. HARVEY (Cornell University). Bioenergetic Aspects of Lizard Herbivory.

Most primarily herbivorous lizards are large species weighing 200 gms or more as adults. In many of these species the juveniles are more carnivorous than the adults. This generalization applies to the families Agamidae, Cordylidae, Gerrhosauridae, Iguanidae, and Scincidae. Weight-specific metabolic rate (MR) decreases with increasing body size. A 200 gm lizard would have a MR of 0.11 cc O_2/gm hr. Species with MR lower than this are primarily herbivorous, while those with higher MR are primarily carnivorous. Plant material contains less energy/unit weight than animal matter. I suggest that one factor determining the diet of a lizard species is its MR. A small species cannot obtain enough energy from an herbivorous diet to maintain its high MR. Other considerations include the energetic cost of capturing mobile animals compared to browsing on stationary plants, seasonal availability of food, and inter- and intrespecific competition. There are a few lizards weighing less than 200 gm that are primarily herbivorous. These species have specializations that offset the problems of high weight-specific MR. Modifications of the basic lizard pattern (leglessness, special feeding mechanisms, high MR) are associated with retention of a carnivorous diet.

PYLKA, JOSEPH M., JAMES A. SIMMONS and E. GLEN WEVER (Princeton Univ.). Sound Production and Hearing in the Rattlesnake.

Hearing in Crotalus v. viridis and sound production in nine species of Crotalus and Sistrurus were studied.

Sensitivity of the ear of C. v. viridis to airborne sound was studied by the cochlear potential method. This species is moderately sensitive to low tones between 80 and 400 Hz., and is insensitive to tones above 1 KHz.

The rattle of this species is a broadband noise generator producing most of its energy between 2 and 50 KHz. Little energy is produced below 1600 Hz. Total sound pressure level is 34 db re 1 dyne/sq. cm. Rattle frequency spectra of 8 other species of rattlesnakes were similar in exhibiting high levels at ultrasonic frequencies.

In addition to functioning passively as a warning signal, the rattle may also actively repel a potential mammalian predator by producing an intolerably loud sound field. By segregating its rattle frequency range from its hearing range, the rattlesnake may preserve the usefulness of this sensory modality.

RHOTEN, WILLIAM B. (Washington Univ.). The morphology of reptilian pancreatic islets as observed by light and electron microscopy.

Three major cell types have consistently been identified by light and electron microscopy of reptilian pancreatic islets. Four examples of three extant orders will be discussed: Anolis carolinensis and Laticauda semifasciata (Squamata), Caiman fuscus (Crocodilia), and Pseudemys scripta (Testudines). The tinctorial properties of the three cell types at the light microscopic level are similar in all animals, as determined by staining with aldehyde fuchsin-trichrome(AF-T) and phosphotungstic acid-hematoxylin(PTAH), or by silver impregnation. The A cells were ponceau-acid fuchsin and PTAH positive, and did not blacken with the silver method used. B cells were aldehyde fuchsin reactive and gave a negative reaction with PTAH or silver nitrate. D cells were stained pale green in AF-T preparations and were blackened by silver. At the electron microscopic level, A cells usually contained large, electron opaque secretory granules which were round to oval in profile. The secretory granules of B cells were of variable morphology, but usually round with diversified internal profiles. D cells usually had the smallest, in diameter, secretory granules of the three major cell types, but in Anolis the D granules were large. In addition, D granules had a round profile and a moderately electron opaque matrix separated from the limiting membrane by a narrow electron lucent space. The number and distribution of A, B, and D cells are similar by light and electron microscopy. (Grants:AM11407,GM00897)

SHOOP, C. ROBERT and THOMAS L. DOTY (U. Rhode Island). Inverse correlation of Rana sylvatica and Ambystoma opacum larval survivorship.

Adult and larval population of wood frogs (Rana sylvatica) and marbled salamanders (Ambystoma opacum) were studied over a two year period. The breeding pond was surrounded by a fence with traps along each face. Predation on Rana eggs, embryos, and tadpoles by A. opacum was observed during the first year. High embryo mortality of A. opacum the second year corresponded with an almost 50 fold increase in R. sylvatica surviorship to the dispersal stage. Relative number of other potential Rana predators were similar each year. These data indicate that A. opacum may play a major role in regulation of the R. sylvatica larval population size.

SMITH, GARY C. (Furman Univ.). Ecological energetics of three ectothermic vertebrates.

Comparisons were made of the energy budgets of three ectothermic vertebrates found in Southeastern U.S. The three species studied were Elaphe guttata, Heterodon platyrhinos and Bufo terrestris. Values for assimilation, ingestion, growth, shedding, metabolism and reproduction were converted to caloric units and integrated into energy flow models for each species. Assimilation efficiencies for the three species were 88.9 per cent for E. guttata, 83.9 percent for H. platyrhinos, and 73.7 per cent for B. terrestris. Regression slopes of metabolism per animal hr. for the three species were 0.70 for corn snakes, 0.79 for southern toads, and 1.04 for hognosed snakes. Reserves of fat in the fat bodies were lowest in the spring for all species and coincided with periods of maximal reproduction. Egg clutches comprised approximately 42 per cent of the total caloric value of the females of all three species. Comparisons of energy flow in the three species revealed that ingestion methods (A= I - E) gave significantly higher and more reliable results than production-respiration methods (A= P + R) for all three species.

SPOTILA, JAMES R. and PAUL W. LOMMEN (U. of Michigan). Biophysical Ecology of Large Reptiles: A Mathematical Model for Heat Flow Within the Body.

A mathematical model for heat conduction through large reptiles was developed. The animal was considered to be a large cylinder with a central core surrounded by several layers of insulating muscle and fat. The number and thicknesses of these layers were changed and different conductivity values were used in order to account for the effects of changes in heart rate, vaso -dilation, vaso -constriction, variations in the conductivity of flesh, and other physiological parameters that affect heat flow in real animals. The model relied on an iterative mathematical procedure in which heat in, heat out and heat stored were determined for each layer and the core during a specified time period. This yielded the final temperatures of the core, insulating layers, and outer surface at the end of the time period. A reptile with a central core diameter of 80 cm surrounded by several layers of insulation 10 cm thick, would show a diurnal change in deep body temperature of 0.77°C if exposed to the thermal and radiative environment of a typical mid-July day in south Florida. Such large reptiles would approach the condition of homeothermy due to their large body size. Seasonal changes in the physical environment would be more important than short term changes.

THROCKMORTON, GAYLORD S. (Univ. of Chicago) Digestive Efficiency in the Herbivorous Lizard Ctenosaura pectinata

Food passage rates and digestibility coefficients ($\frac{\text{cal. consumed - cal. excreted}}{\text{cal. consumed}} \times 100$) were determined for four specimens of Ctenosaura pectinata fed sweet potatoes (Inpomea batatas) over a six week period. Body temperature was recorded continuously for 24-hour intervals at various times throughout the study. The animals were weighed at two-week intervals. Kodak Opaque red pigment was used as a marker to determine the rates of food passage and to mark the beginning and end of collecting periods. Collecting periods averaged seven days. Preliminary results suggest that the apparent digestibility coefficient for Ctenosaura pectinata fed sweet potato is approximately 82%. The animals maintained themselves within an average daytime temperature range between 36° - 39°C. The weight change for the animals in a two-week period was 1-5% of total body weight. The food passage rate under these conditions was four days.

TILLEY, STEPHEN G. (Smith Coll.). Comments on the distribution of Desmognathus fuscus in the southern Appalachian Mountains.

A desmognathine salamander, here referred to Desmognathus fuscus Green, inhabits small streams and seepages at intermediate elevations in the Great Smoky and Unicoi Mountains of North Carolina and Tennessee, and the Whitetop-Mt. Rogers area of Virginia. While it may occur in other ranges along the northwestern border of the southern Blue Ridge, search for it in the Unaka Mountains and ranges southwest of the Unicois has been unsuccessful. It likewise appears to be absent in the interior of the southern Blue Ridge Physiographic Province. It is an abundant salamander in the Great Smoky Mountains, where previous reports of its absence may stem from its similarity to D. ochrophaeus and D. monticola. Experience with D. fuscus in two drainage systems in the Great Smokies indicates that it may be replaced ecologically by D. ochrophaeus at high elevations, while at intermediate elevations it displaces D. ochrophaeus from the types of brooding sites utilized by that species elsewhere in the southern Appalachians. The rarity of D. fuscus at low elevations may result from scarcity of proper habitat, but the factors restricting its general distribution in the southern Blue Ridge are otherwise obscure.

TILLEY, STEPHEN G. AND MARY G. ALTALO (Smith Coll.). Repression of egg-eating behavior in brooding females of Desmognathus ochrophaeus.

The salamander Desmognathus ochrophaeus exhibits oophagy in the laboratory and in the field. Females actively brooding their clutches repress the tendency to consume live eggs, of their own or of foreign clutches. Feeding is not repressed with the onset of brooding behavior, but is restricted by suppression of foraging activity. Repression of oophagy in brooding females is thus not due to a general suppression of feeding activity. The presence of a dead egg in her clutch may incited a brooding female to resume oophagy, which may result in the consumption of a few live eggs after consumption of the dead one. Disturbed females may also consume their eggs. Brooding females discriminate between live eggs and other food, between live and dead eggs, and between newly hatched larvae and other food. The presence of the female's clutch seems to be an important factor in the repression of oophagy. Males, gravid and non-gravid females, brooding females taken from their clutches, and juveniles do not discriminate between any of the above and actively feed upon eggs of their own species.

WAKE, DAVID B. (Univ. of California, Berkeley) and LOMBARD, R. ERIC (Univ. of So. California). Functional aspects of tongue projection mechanisms in plethodontid salamanders.

Mechanisms for rapid, long-distance projection of the tongue have evolved in two groups of plethodontid salamanders, the Hemidactyliini and Bolitoglossini. Both have free tongues, long epibranchial cartilages, large projection muscles and specialized intrinsic tongue musculature. The groups differ from each other in several important ways. Special features of this apparatus in dynamic sequence follow: 1) a bulb-like Subarcualis rectus I muscle squeezes the tapered epibranchial to propel the hyobranchial apparatus and tongue pad out of the mouth; 2) paired tractriform channels passively collapse the expanded hyobranchial apparatus and determine the angle of projection; 3) tendons lock the apparatus in a folded, linearly compact form upon compression; 4) a modified Rectus abdominis muscle, extending uninterruptedly from the pelvis to the tongue, is carried out of a complex coil and contracts to instantly return the apparatus to the mouth. In the hemidactyliines a muscle unlocks the apparatus as it is retracted; this muscle is lacking in the bolitoglossines where unlocking is passive. In bolitoglossines the projection channel is extended anteriorly and forms a muscular cylinder. This acts as an efficient aiming device. Lubrication is provided by serous glands on the ventral surface of the tongue pad (Supported by NSF Grant GB 17112).

WEIGMANN, DIANA L. and RONALD ALTIG (Miss. St. U.) Anoxic tolerances of five species of larval amphibians.

Specimens were subjected to anoxic water for specified periods of time and then removed to water at room conditions for one-half hour. Then the number of dead specimens (ecological plus absolute) were counted. Survival under these conditions was used as an index of ecological tolerances and preferenda of the species tested. Results generally agree with what is known of the ecology of the species, e.g., small Siren intermedia and large Ambystoma maculatum were similar and much more tolerant than tadpoles of Gastrophryne carolinensis, Acris gryllus, or Hyla chrysoscelis.

CURRENT HERPETOLOGICAL TITLES, XVIII: 1970 - 1971

Herpetological Information Search Systems
American Museum of Natural History
New York, New York 10024

We have brought to your attention more than 13,000 current titles in the pages of this journal to date.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any current paper (e.g., 1970-1971) that is concerned with a member of a Recent order of amphibians or reptiles.

HERPETOLOGICAL REVIEW has appeared bimonthly, beginning in 1971. This means that the titles published here will be even more current. We hope that the added numbers will serve to reduce the titles-per-issue to a more manageable number.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This list contains titles of books and articles that have come to our attention during the period 17 July through 31 August 1971. Periodical title abbreviations follow the American Standard for Periodical Title Abbreviations Z 39.5-1963 (American National Standards Institute, Inc., New York).

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and L. Greene. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. The library staff of the Museum have continued to aid our project. Special thanks to the members of the Herpetology Department, AMNH for their aid in cross indexing, which allows us to offer new services. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

No commercial computer service yet offers all of the facilities that we need and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 36 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

NEW H I S S SERVICE

HISS is pleased to announce the first issues of its planned series of special bibliographies.

THESE first numbers are no more than offset or xerox lists of titles. We expect to have several cross-indexed publications by the end of 1972.

THE FOLLOWING bibliographies are available now:

CHELONIA MYDAS.
PUBL HERPETOL (1): ca. 300 ref....$3.00

HERPETOLOGICAL TITLES in 1969.
PUBL HERPETOL (2): ca. 4000 ref...$8.00

LONGEVITY OF AMPHIBIANS AND REPTILES. *
PUBL HERPETOL (3): ca. 200 ref....$3.00

CHROMOSOMES OF AMPHIBIANS AND REPTILES. *
PUBL HERPETOL (4): ca. 1000 ref...$5.00

REPRODUCTIVE SYSTEM OF REPTILES.
PUBL HERPETOL (5): ca. 500 ref....$5.00

ALBINISM IN AMPHIBIANS AND REPTILES.
PUBL HERPETOL (6): ca. 200 ref....$3.00

* Updated from the list that will appear in the 1971 Yearbook of Herpetology.

JOURNAL OF HERPETOLOGY,

a leading international periodical on the biology of amphibians and reptiles published by the SSAR, henceforth will be published three times per year. Manuscripts on any aspect of amphibian and reptile biology will be considered for publication; authors need not be Society members. Prospective authors should consult the inside back cover of a recent Journal for other details on manuscript submission.

Editor: J. P. Kennedy, The University of Texas, Graduate School of Biomedical Sciences, Box 20367 Astrodome Station, Houston, Texas 77025 (U.S.A.)
Editorial Board: Albert P. Blair (U.S.A.), Donald G. Broadley (Rhodesia), Charles C. Carpenter (U.S.A.) Hajime Fukada (Japan), Stanley W. Gorham (Canada), Paul Licht (U.S.A.), Murray J. Littlejohn (Australia), William F. Pyburn (U.S.A.), Stanley N. Salthe (U.S.A.), Hobart M. Smith (U.S.A.), Thomas Uzzell (U.S.A.), Robert G. Webb (U.S.A.), Heinz Wermuth (Germany)
Index Editor: Ray D. Burkett (U.S.A.)

Sample titles from some recent issues:

Scale and cranial characteristics of the caecilian Brasilotyphlus, by Edward H. Taylor (U.S.A.)
A field kit for processing and storing amphibians and reptiles, by T. Paul Maslin and Lowell E. Swenson (U.S.A.)
Crisantophis, a new genus for Conophis nevermanni Dunn, by Jaime Villa (Nicaragua)
Inconsistency in application of the biological species concept to disjunct populations of anurans, by Gary C. Packard (U.S.A.)

student prize

A $100 prize will be awarded annually to the author of the best paper by a student published in the preceding year's Journal of Herpetology. As soon as the Selection Committee is established, further details of this award will be announced. Any student papers published in the Journal in 1972 or later qualify for the prize.

subscriptions & membership

All members of the SSAR receive the Journal of Herpetology, issues of the Facsimile Reprints in Herpetology series, and the Society's newsletter, Herpetological Review, as part of their membership. In addition, members receive a $5 discount on all book-length facsimile reprints. Society membership for 1972 costs $8.00 in the United States and Canada, $6.00 in other countries. Those who are able may wish to assist the Society more substantially by becoming sustaining ($10.00) or contributing ($15.00) members. Institutional subscriptions are $16.00. Address all inquiries or dues to Dr. Henri C. Seibert, Treasurer, Department of Zoology, Morton Hall, Ohio University, Athens, Ohio 45701, U.S.A.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

new reprints for 1972

Fitzinger's SYSTEMA REPTILIUM

with an introduction by Robert Mertens (Senckenberg-Museum, Frankfurt)

L. J. Fitzinger's "Systema" ranks as one of the major works in systematic herpetology. Many familiar names are first proposed here, including frogs (Pseudacris, Gastrotheca, Eupsophus, Limnodynastes), turtles (Eretmochelys, Lepidochelys), lizards (Gonatodes, Psammophilus, Conolophus), and snakes (Drymarchon, Lampropeltis, Thamnophis, Leptotyphlops, Leptodeira, Opheodrys, Drymobius, Boiga). This work was important in stabilizing nomenclature, particularly in establishing genero-types for all of the then known amphibians and reptiles (living and extinct) of the world.

About 128 pages, portrait, 6 x 9 inches, index.

Dunn's Salamanders of the family PLETHODONTIDAE

with an introduction by David B. Wake (University of California) and Arden H. Brame (Eaton Canyon Nature Center)

E. R. Dunn's book is a recognized classic, not only because of its species-by-species treatment of this largest family of salamanders, but for its carefully-described methods of procedure and the oft-quoted autobiographical foreward. Each species of salamander, including the tropical and European plethodontids, is fully described with measurements, list of locality records and statements on habits, habitat and distribution. A range map is included for each form. Published in 1926, this book has long been out-of-print and unobtainable. The new introduction provides a modern appraisal of Dunn's work and a useful appendix listing the current name and status of each of the 87 forms in Dunn's book. An index has also been added.

About 472 pages, 3 plates, 86 maps, 6 x 9 inches, index.

● SSAR members before publication
$8 paperbound $10 clothbound

● Institutions; Non-members
$13 paperbound $15 clothbound

to order:

Orders may be placed now. Both books will be published in summer 1972; to take advantage of special prices, SSAR members must place their orders before publication. Please circle edition desired and send with payment to Dr. H. C. Seibert, Publications Secretary, Box HR, Department of Zoology, Morton Hall, Ohio University, Athens, Ohio 45701, U.S.A. Make checks payable to: "SSAR." Receipt sent on request only. Please mark these boxes if you wish to receive information on SSAR membership ☐ or a complete list of Society publications ☐ .

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES
American Museum of Natural History
New York, N.Y. 10024

NAME _____ ORDER NO. _____

ADDRESS _____

_____

_____ ZIP _____

The Catalogue of American Amphibians and Reptiles is a series of loose-leaf accounts, each prepared by an expert in the field. The pages are 8 1/2 x 11 inches, and are punched for standard binders. Each one- to four-page account gives a wealth of information about the animal, including common and scientific names (with a synonymy), a definition, a description, information on fossil occurrence, a detailed map of geographic distribution, and a comprehensive introduction to the literature.

The Catalogue is an essential reference for all biologists who use amphibians or reptiles in their research. The loose-leaf format allows individual additions and up-dating, as well as giving the user the option of arranging the accounts in serial, alphabetic, geographic, or taxonomic order.

One hundred accounts were published from 1963 through 1970. Another 25 (about 60 pages) are to be published in 1971. Most of the accounts are on species that occur in the United States and Canada. Because most of the salamanders of this region have been treated in past issues, future accounts will have greater emphasis on frogs and various reptile groups.

PRICE LIST

	INDIVIDUAL	INSTITUTION
THE CATALOGUE: Imprinted Binder, Taxonomic Tabs, Accounts 1-125 (Includes subscription for 1971).....	$23.00	$27.00

SOCIETY MEMBERSHIPS AND SUBSCRIPTIONS -- 1971

Though their numbers are increasing, it is still true that fewer than 60 per cent of the members of the HERPETOLOGISTS' LEAGUE belong also to the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES. And less than two-thirds of the members of the latter society also belong to the Herpetologists' League. We believe that each of the societies has something important and unique to offer the members of the other. In the interests of a greater combined membership of persons interested in amphibians and reptiles, we invite the members of each society to also join the other.

To ease this process, we offer the "easy-form" membership applications below.

THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

This young society (a 1967 outgrowth of the OHIO HERPETOLOGICAL SOCIETY) offers a number of different publications on amphibians and reptiles.

Its regular publications include the semi-annual JOURNAL OF HERPETOLOGY (about 200 pages per year), the bi-monthly HERPETOLOGICAL REVIEW (about 225 pages per year), and a series of FACSIMILE REPRINTS IN HERPETOLOGY, which is now devoted to reprints of G. A. Boulenger's contributions to American herpetology (about 100 pages per year). In 1971 the Society also assumed sponsorship of the CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES. Besides these publications, the Society issues a number of SPECIAL REPRINTS each year (see the back of this page for examples).

Membership is open to anyone interested in amphibians and reptiles. All classes of members receive the J HERPETOL, HERPETOL REV, regular issues of FACSIMILE REPRINTS, and all have the same membership privileges. The higher classes of membership aid the Society in improving and expanding its services to its members and to the field of herpetology.

[Please make check to "SSAR."]

THE HERPETOLOGISTS' LEAGUE

The Herpetologists' League is the elder and the larger of the two societies. It was established in 1936, when the journal HERPETOLOGICA (now in its 27th Volume) began publication.

HERPETOLOGICA appears quarterly, and will publish some 500 pages of papers on amphibians and reptiles this year. By arrangement with the SSAR, the Members and Fellows of the League also receive HERPETOLOGICAL REVIEW, beginning this year.

Anyone with an interest in herpetology is eligible for membership in the Herpetologists' League. The Fellows, who hold the voting rights in the League, are elected by the Executive Council, "on the basis of their contribution to the science of herpetology."

The Members receive HERPETOLOGICA, to which they can submit manuscripts for publication. They may also attend the Annual Meeting, which usually is held in conjunction with the AAAS meetings.

HERPETOLOGISTS RECORD

CHROMOSOME PREPARATIONS OF AMPHIBIANS AND REPTILES: IMPROVED TECHNIQUE. -- Development in recent years of new techniques or new combinations thereof have allowed efficient examination of bone marrow chromosomes in a variety of vertebrates. James L. Patton (1967, J MAMMAL, vol 48, p 27) described a very useful procedure for mammals, which is often referred to as the colchicine, hypotonic citrate, air dried (or flame dried) technique. Lowe, Wright, and Cole (1966, MAMMAL CHROM NEWSL, no 22, p 201) modified this procedure for efficient use specifically on amphibians and reptiles. Two modifications designed to accommodate working with poikilotherms rather than homeotherms were mentioned in that paper: (1) stress the peripheral circulatory system in order to stimulate blood cell production in the marrow of experimental animals; and (2) incubate the stressed animals for 20 to 30 hours at a temperature approximating their preferred temperature. Two additional modifications that have been used widely are: (1) after placing the extracted marrow into one per cent sodium citrate, allow it to sit at room temperature for 30 minutes; and (2) for anurans, use half the dose of colchicine used for lizards (and other reptiles) (Cole, Lowe, and Wright, 1968, COPEIA, no 1, p 96).

We have been experimenting with intraperitoneal injections of several chemicals in order to improve the stress aspect of this procedure, which is most critical for consistently obtaining dividing marrow cells in acceptable quantities. We have succeeded with three agents: (1) bacterial endotoxin (from Escherichia coli; suggested and donated by Richard K. Root, Chief, Infectious Disease Section, Department of Medicine, University of Pennsylvania School of Medicine, Philadelphia); (2) phenylhydrazine; and (3) an active culsure of yeast. We sought a replacement for the first two agents because they are relatively inconvenient to use and may pose some unnecessary hazards (Dr. Root informed us that phenylhydrazine may be absorbed through human skin and can cause anemia in humans as well as other vertebrates). Thus, we are most pleased with the use of yeast because it clearly provides the desired response (numerous dividing cells), it does not expose ourselves to any risks, and it is inexpensive and readily obtained and applied in the field with a minimum of effort.

We use a commercial yeast (Fleischmann's) that is sold in grocery stores for baking purposes. Thoroughly mix (by means of vigorous shaking in a centrifuge tube) one-half cc yeast and one-half cc table sugar with seven cc luke warm tap water and allow to sit for one-half hour to one hour at room temperature. Thoroughly mix this once again immediately prior to use. Then inject this solution into the experimental animals 20 to 30 hours prior to sacrificing them, and incubate them at the proper preferred temperature after injecting the yeast.

Dosage of the yeast solution varies according to species and size, but it is not so sensitive as to require weighing the animals prior to injection -- "guestimates" of doses consistently suffice. For guidelines, we use 0.5 cc for an average sized Saeloporus undulatus weighing approximately 15 g, 0.8 cc for a Rana pipiens weighing 25 g, and 1.5 cc for a Thamnophis sirtalis weighing 30 g. -- Charles J. Cole and Carol R. Leavens, DEPT HERPETOLOGY, AMER MUS NAT HIST, NEW YORK 10024.

•

In **Bangkok**, some of the citizenry is up in arms over reports that one of **Deputy Prime Minister Prapass Charusathiara's** pet crocodiles has escaped into a canal that people use for bathing. His spokesman said it wasn't so, and that the story, which appeared in an Opposition newspaper, was aimed at embarrassing Mr. Charusathiara. Nevertheless, people along the canal are going bathless, just in case a crocodile is lurking about, and one resident was said to be trying to catch the reptile by using a dog as bait.

TERMITE INSPECTOR FINDS BOA NO BORE

Termite inspectors sometimes find things you would hardly believe, said Robert I. Rush, general manager of Animal Regulation.

Rush made his remarks in announcing an unusual sale scheduled today at the North Hollywood Animal Shelter, 13131 Sherman Way.

A termite inspector crawling under the home of Paul McGuire, 8100 Cedros Ave., Van Nuys, made the sale possible.

He reappeared quickly and was "white as a sheet," according to McGuire.

"You do have strange termites," he blurted before city animal control officer David Leon was summoned.

Leon crawled under the house and captured the 4-foot boa constrictor which will be available for sale today. Purchase price is $3.98 plus a $15 fee for a wild animal permit.

UNREVIEWED-UNEDITED COMMUNICATIONS

A POSSIBLE CASE OF MIMICRY IN FROGS

Craig E. Nelson and Gene A. Miller

Two species of frogs, which may represent a case of mimicry, were collected together approximately one-half mile east of Kanashen, Guyana (1 deg. 47 min. N, 58 deg. 33 min. W). Both species are terrestrial and were captured in midday while fleeing ahead of the field party.

The two species have similar dorsal coloration and flash colors. Lithodytes lineatus (Leptodactylidae) displays broad yellow dorsolateral lines which begin on the snout, extend through the upper eyelid, pass above the forelimb, and terminate at the dorsal edge of the groin. It has red-orange flash spots in the axilla, groin, and on the back of the thigh. The dorsum and venter are otherwise generally black, and the limbs are dark tan with black spots.

Phyllobates femoralis (Dendrobatidae) has yellow dorsolateral lines in the same relative position (but narrower) as those of L. lineatus. It has an orange axillary spot and a short orange stripe which extends from the groin over the base of the thigh and onto its posterior face. P. femoralis has black dorsal coloration with a faint tan wash, and dark tan limbs with dark spots only on the proximal part of the thigh. Unlike L. lineatus, P. femoralis has a creme ventro-lateral stripe which extends from the axilla to the groin, and a black and white mottled venter and a ventro-lateral cream-colored spot below the chin and side.

L. lineatus and P. femoralis have generally congruent ranges along the northwestern margin of the Amazon basin. Cochran and Goin (1970) cite specimens of L. lineatus from Ecuador, Colombia, and Guyana, and of P. femoralis from Peru, Guyana, and Colombia. Rivero (1961) lists Venezuela and Trinidad for L. lineatus -- regions where P. femoralis has not been reported. Dr. James P. Bogert (personal communication) reports both species from Iparia, Peru, and Dr. William E. Duellman (personal communication) reports both from Santa Cecelia, Ecuador.

Phyllobates are noted for their extremely toxic skin secretions (Savage, 1966). L. lineatus has the dorsal surfaces studded or shagreened with small glandular tubercles (Rivero, 1961; Cochran and Goin, 1970); this suggests that it might also have protective dermal secretions. If the resemblances between L. lineatus and P. femoralis are mimetic, it might thus be either Batesian or Mullerian.

The only other case of mimicry thus far suggested for amphibians is in salamanders (Huheey, 1960; Huheey and Brandon, 1961; Orr, 1967, 1968).

ACKNOWLEDGEMENTS: Mr. Steve Edwards identified the Phyllobates. Reverend H. R. Ketchem facilitated work at Kanashen. The field work was supported by National Science Foundation Grant GB-6204.

THE HEMIPENIS OF THE ONION-TAIL GECKO *THECADACTYLUS RAPICAUDUS* (HOUTTUYN)

H.G. Dowling, T.C. Majupuria, & F.W. Gibson

Although Cope (1896) was able to present a remarkably clear summary of the hemipenial morphology of lizards in his single study of this subject, some of the individual descriptions are erroneous or misleading. /This is not surprising, considering the poorly-prepared material and primitive optical equipment available to him./

He described (1896: 464) the hemipenes of gekkonids as follows: "In these the organ is short and wide, appropriately to the fragility of the tail. It is also more or less deeply divided into two branches. The entire surface is calyculate, generally minutely so. In *Thecadactylus* each fork has three strong welts. "[etc.]

Although portions of Cope's descriptions were carried over into later systematic works (e.g., Camp, 1923), no subsequent worker appears to have reexamined the hemipenis of *Thecadactylus rapicaudus*. We present here a re-description of the hemipenis of this species, because in some important respects our observations differ from Cope's report. The description is drawn from examination of three everted specimens prepared from fresh material (HGD 797, 798; Trinidad) and the dissection of two preserved specimens (AMNH 64526, 64527) to determine the aspect of the inverted organ and the origin of the retractor muscles.

The hemipenis is short, with the breadth of the two lateral lobes about equal to the total length of the organ (length and breadth of one specimen are each 10 mm). The muscle retractor penis originates on the first (postcloacal) caudal vertebra. As in most lizard hemipenes, the organ can be differentiated into three regions: base, pedicil, and capitulum. The unornamented base and the folds that differentiate it from the pedicil were obscured by the tied thread in the prepared specimens, and are not shown in the figure (Fig. 1).

The sub-cylindrical pedicil has a slightly granular surface, but is essentially unornamented. The lips of the sulcus are distinctly raised, but are also unornamented in the pedicil region. The capitulum is extremely well-distinguished, and is almost completely restricted to the sulcate (medial) side of the organ. It is made up of two large auriculate lobes that are connected across the apex by a third, transverse lobe. The lateral lobes are ornamented with very small, spinulose calyces that are largest at the edges of the lobes and smallest toward their centers (but some of the calyces near the sulcus also are enlarged). The calyculate areas of the sulcate side are separated from the unornamented asulcate side by a fairly well-defined flounce, giving much the appearance of the "capitate" hemipenes of certain South American snakes (Dowling & Savage, 1960: Fig. 63).

The sulcus spermaticus extends from the base of the organ in a straight line toward the apex. When it reaches the capitulum it appears to give off a branch onto each lateral lobe and then continues for a short distance onto the transverse, apical lobe. Each of the lateral branches occupies a deep furrow in a central, depressed area of the lateral lobes. This trifurcate nature of the sulcus does not appear to have been noted previously.

Cope (1896: 464) apparently did not observe the apical (transverse) lobe of the capitulum in his preparations, and thus also missed the trifurcate nature of the sulcus. The entire organ is more accurately described as trifid rather than "divided into two branches." Rather than the "entire surface /being/ calyculate," these structures are restricted to the sulcate side of the lateral lobes of the capitulum. The "welts" seen by Cope in his inverted preparations apparently become the raised edges of the lateral lobes in everted preparations.

The features described for *Thecadactylus* appear distinctive among the hemipenes studied to date, but additional lizards of the Family Gekkonidae will have to be studied to determine what phyletic value can be placed upon them.

This paper is Contribution Number 2 of a proposed series of studies on the hemipenes of the Sauria (see Literature Cited for Number 1). We thank Charles W. Myers for his comments on the paper, Richard G. Zweifel, Chairman, Department of Herpetology, American Museum of Natural History (AMNH) for providing space and facilities, and Robert G. Goelet, President of the New York Zoological Society, for making possible Majupuria's stay in the United States. Some of the specimens are in the private collection of H. G. Dowling (HGD).

NOTEWORTHY HERPETOLOGICAL RECORDS FROM HONDURAS

Donald E. Hahn

Herpetological collecting trips were made to Honduras during August of 1969 and June of 1971. I was accompanied by Dr. and Mrs. Larry D. Wilson on the first trip, and the greatest bulk of time was spent collecting on the Bay Islands, with short trips to departmentos Choluteca, Francisco Morazan, and Olancho. The results of the Bay Island collections are being reported on separately by Wilson and myself. In 1971 the late Mr. Robin L. Dutson and I collected 555 specimens in the deptos. Copan, Comayagua, Cortes, El Paraiso, Francisco Morazan, Islas de La Bahia, La Paz, Lempira, Ocotepeque, and Santa Barbara. A few of these represent noteworthy range extentions or are uncommon species known from only a few localities.

The herpetofauna of Honduras, long poorly known, has recently been the subject of extensive studies by Drs. John R. Meyer and Larry D. Wilson, hopefully to be published soon. The following records add to the information in Meyer's doctoral dissertation, "A Biogeographic Study of the Amphibians and Reptiles of Honduras," 1969, Univ. Southern California, 589 pp.

Special attention should be given to our collections made in deptos. Lempira and La Paz along the border with El Salvador, which, herpetologically speaking, undoubtedly represent two of the more poorly known areas in the country. The known herpetofauna of Depto. La Paz, for exgmple, consisted of only two species, Elaphe triaspis and Centrolenella fleischmanni. Marcala, a small town in southwestern La Paz, is at approximately 2330 meters elevation in the coffee zone at the lower edge of the pine area. A deep swift stream flows through town and most of the immediate area has been cleared and planted in coffee and bananas. The following species were taken in the vicinity of Marcala and all but the Centrolenella represent new departmental records:

Rana pipiens
Hyla staufferi
Smilisca baudinii
Bufo coccifer
Bufo marinus
Leptodactylus melanonotus
Physalaemus pustulosa
Hypopachus variolosus
Centrolenella fleischmanni
Kinosternon scorpioides
Anolis crassulus
Anolis tropidonotus
Basiliscus vittatus
Sceloporus variabilis
Dryadophis dorsalis
Leptodeira annulata

Anolis crassulus (DEH 7123) was previously known from Honduras only from the immediate area about La Esperanza, Depto. Intibuca. Sceloporus squamosus (DEH 7052) was also taken in Depto. La Paz at 1 km. E La Paz (town).

The previously known herpetofauna of the Depto. Lempira consisted of 1 turtle, 5 lizards, and 6 snakes, all from the vicinity of Gracias. Erandique, a small opal mining town in southeastern Lempira lies at about the same elevation as Marcala and is also surrounded by pines. Species collected there include:

*Rana pipiens
*Bufo coccifer
*Bufo marinus
*Physalaemus pustulosa
*Leptodactylus melanonotus
*Mabuya mabouya
Ameiva undulata
*Anolis laeviventris
*Anolis sericeus
*Basiliscus vittatus
Sceloporus variabilis
*Dryadophis dorsalis

An * indicates this species had not been previously recorded from this department.

The Erandique record for Anolis laeviventris (DEH 7285) is the third for Honduras, the other localities being in deptos. Intibuca and Francisco Morazan. This specimen was taken on a rock wall in a pine area.

The collection made in Gracias, Depto. Lempira, consisted of only three species: Bufo marinus, Sceloporus variabilis, and Mabuya mabouya.

Records of note from other portions of the country include the following:

Gonatodes fuscus. Depto. Francisco Morazan: Tegucigalpa (DEH 6143-47). Meyer (1969) listed only two localities for this lizard in Honduras, one from the Caribbean coast (Depto. Colon: Trujillo) and the other from the Pacific coast (Depto. Valle: San Lorenzo). The Tegucigalpa specimens were taken from cracks in buildings along the Choluteca River, which flows through the city. This is the first inland record for this lizard in Honduras.

Sphaerodactylus continentalis. Depto. Comayagua: Pito Solo (DEH 7003). This specimen represents a southern range for Honduras and a departmental record. This lizard was taken from a bromiliad along Lake Yojoa.

Sphaerodactylus dunni. Depto. Cortes: Mts. west of San Pedro Sula (DEH 6925). This is the third locality from which this little-known species has been taken. It was found climbing on a road cut just below the cloud forest in the late afternoon.

Lampropeltis triangulum. Depto. Copan: Copan at Ruins (DEH 6957). This species has not previously been recorded from this

department, and is known from only nine other localities in Honduras.

Pliocercus elapoides. Depto. Comayagua: 7 km. SE Taulabe (DEH 6985). This snake was previously known from only three localities in Honduras, all in Depto. Yoro. The specimen was found DOR in the early morning in a pine area.

Sibon carri. Depto. Francisco Morazan: 66.5 km. S Tegucigalpa (DEH 6176). This specimen represents the fourth known Honduran locality for this rare snake. It was taken AOR during a light rain at night.

Bothrops godmani. Depto. Francisco Morazan: Cerro La Tigra, ca. 10 mi. NNE Tegucigalpa (DEH 7026). This is the seventh locality from which this uncommon species has been taken in Honduras. It was taken at the base of a waterfall in cloud forest. The specimen disgorged a large rodent upon capture.

I would like to thank Dr. Wilson for reading this manuscript and offering helpful suggestions, as well as examining many of my specimens. Dr. Meyer also has my appreciation for identifying a number of specimens.

Herpetologists
c/o Herpetological Review

Dear Sirs:

The University of Kansas is seeking candidates for two vacancies (effective 1 July 1972) in the Division of Biological Sciences. Each position consists of a half-time appointment in both the Museum of Natural History and Department of Systematics and Ecology.

One of the positions is in Herpetology, the other in Mammalogy; each carries the title of Curator in its respective Division. The new Curator of Herpetology will be associated with Dr. William Duellman, and the new Curator of Mammals will be associated with Dr. Robert Hoffmann.

Research interests of candidates should be in one or more of the following fields:

1. Quantitative and theoretical ecology.

2. Quantitative systematics.

3. Functional morphology and biomechanics.

One of the two successful candidates must have a background in multivariate statistics.

Teaching duties will include courses in the area of research specialty, and will, from time to time, involve undergraduate biology courses.

Duties, rank, and salary will be commensurate with qualifications and experience. Candidates should send one copy of their curriculum vitae, four letters of recommendation, reprints of recent publications, and any other supporting documents they wish to Robert S. Hoffmann, Chairman, Department of Systematics and Ecology, University of Kansas, Lawrence, Kansas 66044.

A. J. Rowell, Convenor
Systematics and Ecology
Search Committee

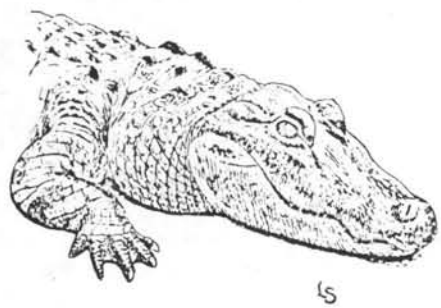
BOOK REVIEW

THE LAST OF THE RULING REPTILES. By Wilfred T. Neill, 1971. Columbia University Press, New York and London. xvii + 486 pp., 162 fig. $15.95.



This book might well be subtitled "All you wanted to know about crocodilians now that it's too late." The inheritors of the archosaurian lineage are nearing extinction throughout the world, and this may be the last book about them to be written by someone with first hand knowledge of most of the living species in the field or in captivity. Wilfred Neill is not only a herpetologist of vast experience; he is also knowledgeable and literate in several other areas of biology and in anthropology, and this book reflects the breadth of his experience.

His main thesis is that few herpetologists have studied living crocodilians in the field, and those who have done so have often been unduly influenced by preconceived ideas, anthropomorphism, and folklore. Other scientists have accepted their observations uncritically and in some cases extrapolated from them until a great deal of erroneous information on the biology of crocodilians is current in the scientific community. This theme introduces the book and is elaborated on in the fourth section which deals extensively with the natural history of the American alligator. Whether one accepts Neill's views or not, it is clear that some reevaluation is in order on such topics as nesting habits of crocodilians and defense of young, alligator bellowing and the vocalizations of other species, the significance of the musk glands, gastroliths, and various food items, and the territorial behavior of these reptiles. Neill himself is not entirely consistent. In some chapters he stresses the stereotyped, unvarying nature of crocodilian behavior patterns; in others he cites examples of how these patterns can be rapidly changed by contact with man.

Other sections of the book include an excellent summary of the fossil history of the Crocodilia and their ancestors, some provocative thoughts on crocodilian distribution and ecology, and a somewhat irrelevant chapter on bipediality in reptiles. The final section of the book treats sequentially all the existing crocodilian species except the American alligator. While some accounts, notably those of the American crocodile, estuarine crocodile, and New Guinea crocodile, are better than others, this is the best single source of information on the little known crocodiles and alligators of the world. There is an excellent bibliography. The book is profusely illustrated. Nearly every crocodilian species is depicted, often as an adult and a juvenile, and skulls of both Recent and extinct species are figured. There are interesting photographs of crocodilian habitats and behavior and distribution maps for every species. Intermixed with these are photographs of a variety of other creatures from caterpillars to sea birds that are, in many cases, only tangential to the main theme of the book.

Neill is pessimistic as to the future of the crocodilians. He predicts that all will be extinct as wild animals by the end of this century as a result of hide-hunting and the modification of habitat. The last pages of his text should be read by those who popularize the cause of ecology and conservation. Personally I believe that most of the world's crocodilians can yet be saved in small enclaves, although their role in shaping tropical ecosystems is about played out. They are nevertheless worth saving as survivors of an ancient era that have left their mark on human culture. When the last crocodilian vanishes from the earth, man's world will be, in some subtle way, diminished.

BOOK REVIEW

AMPHIBIANS AND REPTILES OF KENTUCKY. By Roger W. Barbour. University of Kentucky Press, Lexington 40506. x + 334 pp. 110 color and 127 black & white photographs plus maps.

Profusely illustrated with 237 photographs (110 in color), this book fills a geographic gap in our knowledge of the herpetofauna of eastern North America, and provides the layman with an easy-to-read text on the 99 species of reptiles and amphibians found in Kentucky. The excellent color photographs of each species are a feature not previously available in any popular "state" herpetology. The species accounts are well organized with sections on recognition, variation, habitat, comments on Kentucky distribution, life history, and remarks. A map for each species shows its entire range in the United States.

The author has written this book to "enable a non-professional to identify any

amphibian or reptile native to Kentucky and to enable him to learn something of its distribution and life history." He has partially succeeded in fulfilling those objectives. The keys are comprehensive and, coupled with the numerous photographs, should allow easy identification of all adult species of Kentucky herpetofauna. Unfortunately, there are no keys to larval salamanders or tadpoles, although a brief description of these is usually included under life history. The life histories are as complete as our varying knowledge of the life styles of reptile and amphibian species permits. Information for the layman on the distribution of these animals in Kentucky leaves much to be desired. An understanding of the distribution of reptiles and amphibians in Kentucky would have been greatly enhanced by the use of Kentucky range maps only, instead of showing the entire range of each species in the United States, since this latter range is easily determined by using Conant's Field Guide to the Reptiles and Amphibians (1958).

Certain other basic improvements (along with the addition of more specific range maps) might have been made. This book is written for the non-professional. As such it is unfortunate that the author did not rigidly adhere to standardized common names (i.e. 1956, Conant et al. Common names for North American amphibians and reptiles, Copeia 3: 172-185). I noted twenty common names at the beginning of species accounts which do not conform to the current standardized names in use, the most obvious of which was the incorrect common name "Rattlesnake" (p. 314) for Crotalus horridus instead of the correct name "Timber Rattlesnake." Standardization of common names must be followed if herpetologists are to bring about stability in use of these terms.

The introduction is rather short, and acknowledgements are virtually non-existent. The table of contents is nearly useless due to its brevity. Contents for a book of this nature would be more useful if pagination were included for at least each genus mentioned. For example, a person turning to the Colubridae on page 225 is confronted with a section covering 78 pages and 28 species of snakes! Further, the table of contents assumes that the layman is familiar with reptiles and amphibians at the familial level, whereas most non-professionals would find a listing of the standardized common names much more useful.

This book would have been greatly improved by the inclusion of a history of herpetological exploration of the state of Kentucky including information about the work of investigators such as Rafinesque, Garman, and Funkhouser. This type of information added importantly to recent state herpetological works such as those by Smith (1961, The amphibians and reptiles of Illinois, Illinois Nat. Hist. Surv. Bull. 28(1): 298 pp.) and Webb (1970, Reptiles of Oklahoma, Stovall Mus. Pub. 2: 370 pp.).

The author refers frequently in the species accounts to the various physiographic provinces in Kentucky and includes a map of these (on page 8), but unfortunately does not include a detailed description of the actual physiographic provinces in Kentucky nor does he discuss their influence on the distribution of the total herpetofauna of the state. It has been proposed by Hirschfeld (1963, The Bluegrass Physiographic Province and its influence upon the distribution of Kentucky amphibians and reptiles, Journ. Ohio Herp. Soc. 4(1-2): 63) that certain reptiles and amphibians avoid the Bluegrass Physiographic Province in Kentucky, and a detailed discussion of this aspect of Kentucky herpetology alone would be valuable.

Little or passing mention is made by the author on subspecific and specific variation in the species of reptiles and amphibians in Kentucky. Detailed analysis of variation of many forms occuring in Kentucky such as Notophthalmus viridescens, Desmognathus fuscus, Plethodon dorsalis, Rana clamitans, Pseudacris triseriata, Kinosternon subrubrum, Chrysemys scripta, Diadophis punctatus, Coluber constrictor, Elaphe obsoleta, Lampropeltis getulus, Lampropeltis doliata (=Lampropeltis triangulum), Storeria dekayi, Natrix erythrogaster, Natrix sipedon, Agkistrodon contortrix, and Crotalus horridus would contribute much to an understanding of character variation in these species not only in Kentucky but throughout their entire range. An example is a recent paper on Virginia valeriae in Kentucky (Pisani and Collins, 1971, the smooth earth snake, Virginia valeriae (Baird & Girard), in Kentucky, Trans. Kentucky Acad. Sci. 3(1-2): 16-25) which shows that the two subspecies of this form in Kentucky appear to be separated by a hiatus in their range and exhibit no evidence of intergradation although previous workers show their range as meeting in Kentucky and indicate that intergradation takes place over a broad area.

The selected bibliography contains over 180 entries, most of which pertain directly to Kentucky herpetology or which definitely contain references to the state's herpetofauna. This listing, however, is by no means complete. I am aware of over 350 specific citations on Kentucky reptiles and amphibians in the literature.

In summation, the book overall is a definite contribution to knowledge of the reptiles and amphibians of Kentucky, but much remains to be done before a detailed understanding of distribution, specific and subspecific variation, and life history, will be available for the herpetofauna of the Commonwealth of Kentucky.

HERPETOLOGY AT NOTRE DAME

Studies on the biology of amphibians and reptiles at Notre Dame have continued to broaden with the addition of new faculty and facilities, especially in the areas of behavior, physiology and anatomy. The new Life Sciences Building, which triples the biology department's space, is now completed and occupied; this offers an exceptionally well instrumented and integrated structure for most types of modern research. Special facilities available specifically for herpetological work include several programmable environmental chambers, cold rooms, recording and data processing equipment, apparatus for rearing and maintaining living animals, and extensive reprint collections. Additional training and testing tanks for studies on photoreception and orientation are now being built on the roof of the building.

ROBERT E. GORDON (PhD Tulane) continues his studies on locomotor activity of salamanders and lizards, as well as his work on the breeding biology of the green salamander (Aneides aeneus). JOSEPH A. TIHEN (PhD Rochester) has returned to his paleontological studies, having completed a five-year term as editor-in-chief of the American Midland Naturalist, a journal published by this department. Tihen's current interests center around the Miocene faunas of Montana and the relationships and history of Tertiary North American salamandrids. He also maintains his interest in the evolution of the toads of the genus Bufo. KRAIG ADLER (PhD Michigan) pursues his systematic and biogeographic studies on the herpetofauna of southern Mexican cloud forests and his work on the reproductive biology of tropical plethodontid salamanders. His primary research interests concern light receptors (especially extraoptic ones) and environmental cues used by amphibians and reptiles in activity rhythms and for compass orientation, studies recently funded by the NSF. DOUGLAS H. TAYLOR (PhD Mississippi State) was lately associated with Adler on a 15-month NSF postdoctoral fellowship, studying the involvement of the plane of polarized light and the use of pineal photoreceptors in amphibian orientation. Adler and Taylor filmed much of this work, preparatory to making a documentary on orientation mechanisms in lower vertebrates to be deposited with the behavioral films lending library at Pennsylvania State University. Taylor has now taken a position as assistant professor of zoology of Miami University. SUE A. BINKLEY (PhD Texas) has been involved in some of the amphibian rhythm work with Adler and Taylor, especially in developing new techniques for the analysis of rhythmic data much of which will appear in her forthcoming book on rhythm analyses. KENYON S. TWEEDELL (PhD Illinois) is continuing his research on amphibian pathology, specifically the transmission of renal tumors in frogs. Two newly appointed faculty members also concern themselves with amphibians and reptiles. THOMAS L. POULSON (PhD Michigan), in addition to his major interests in the physiological ecology of cave organisms, has studied the respiratory physiology of lizards. ROBERT P. FIORINDO (PhD California at Berkeley), an endocrinologist, is studying the hypothalamic control of prolactin secretion in reptiles and other vertebrates.

A descriptive brochure on the department and its graduate program may be obtained on request from the Administrative Assistant, Department of Biology, University of Notre Dame, Notre Dame, Indiana 46556, USA. A list of available papers on lower vertebrates by Notre Dame faculty and students can be obtained from the same source.

MEETINGS AND SOCIETIES

CALENDAR 1972

June.....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Boston.

July.....SALAMANDER SYMPOSIUM, Highlands Biological Station, North Carolina.

August...Combined Meeting: HERPETOLOGISTS' LEAGUE AND SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES, University of Oklahoma Biological Station, Lake Texoma.

24-30 September...INTERNATIONAL CONGRESS OF ZOOLOGY, Monaco.

CALENDAR 1973

4-11 August FIRST INTERNATIONAL CONGRESS OF SYSTEMATIC AND EVOLUTIONARY BIOLOGY, Boulder, Colorado.

INDIVIDUALS AND INSTITUTIONS

MAX A. NICKERSON has moved from Arkansas State University to Head of the Vertebrate Division, Milwaukee Public Museum.

K. V. THIRUVATHUKAL (Lewis Coll., Lockport, IL) and his students have been studying the thymus glands of snakes and Necturus.

CLIFFORD R. JOHNSON has moved from the University of Queensland to the University of New England (Armidale, N.S.W., Australia) where he has a fellowship, with GRAHAM WEBB, to work on the role of cardiac flow-pattern in reptilian thermoregulation and oxygen transport.

Mr. & Mrs. STEPHEN WINKSELBAUM (3010 Clarendon Rd., Brooklyn, NY) announce the birth of a daughter, NAJA KATHLEEN, on 14 September.

WILLIAM H. WOODIN announced his retirement as Director, Arizona-Sonora Museum. His successor is MERVIN W. LARSON.

THE SOCIETY OF THE SIGMA XI

The Society of the Sigma XI announced today through the Chairman of its Grants-in-aid of Research Committee, Dr. Harold G. Cassidy, an award to Mr. Steven P. Christman of the University of Florida, Gainesville.

This award has been made to Mr. Christman to assist him in his study of "Biogeography of Florida reptiles."

Dr. Cassidy, in making this announcement, stated "Sigma XI each year makes a number of grants to promising scientists at critical points in their research careers. We recognize that many needs are relatively too small for the large foundations to consider, yet to the scientist himself the need may be critical. It is to meet these needs that our research fund is maintained."

ALSO IN 1970-72

Jeffrey H. Black, University of Oklahoma. A survey of the subterranean invertebrate fauna of limestone and gypsum caves in Oklahoma. $200.

Donald R. Clark, Jr., Texas A & M University. A radio-telemetric study of movements and thermal ecology of two species of large snakes. $100.

Elizabeth K. Blatt, Concord College, Athens, West Virginia. Melatonin concentration in the brain of stirnorganectomized. *Rana pipiens*. $200.

James P. Bogart, Louisiana Tech University. Effect on chromosomes in tadpoles caused by irradiation of developing gametes in parent frogs. $200.

Edmund D. Brodie, Jr., Clemson University. Defensive behavior of salamanders of the genus *Ambystoma*. $250.

Stephen R. Edwards, University of Kansas. Quantitative phyletics of the genus *Colostethus* (Anura: Dendrobatidae). $200.

William H. Gehrmann, Tarleton State College, Stephenville, Texas. Sites of extrathyroidal iodine fixation in the cervical region of the collared lizard *Crotaphytus collaris*. $100.

Ronald C. Gratz, University of Notre Dame. The effects of incubation temperature on scutellation in the lizard *Anolis carolinensis* (Lacertilia: Iguanidae). $100.

(TO BE CONTINUED.)

MEMBERS DESIDERATA

LINDA E. MAXSON (Dept. of Biochemistry, Univ. of Calif. Berkeley, 94720) would like to receive live South American hylids or serum samples for immunological studies. Locality data would be appreciated.

MEMBERSHIP IN THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles.

Regular dues are $8 for persons living in the United States and Canada, $6 for those in other countries.
Sustaining Members pay $10, and Contributing Members $15.
Institutional Subscription, $16.

Write: HENRI C. SEIBERT
Treasurer, SSAR
Department of Biology
Ohio University
Athens, Ohio 45701

MEMBERSHIP IN THE HERPETOLOGISTS' LEAGUE

All persons interested in herpetology are eligible for membership.

Dues are $8 for Regular Members, $10 for Fellows. Institutional Subscription, $15.

Write:
HOBART F. LANDRETH, Secty-Treas.
Herpetologists' League
Department of Zoology
University of Oklahoma
Norman, OK 73069

SUBSCRIPTION TO THE CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

A loose-leaf series of species accounts of the amphibians and reptiles of the Americas, with special emphasis on those in the United States and Canada.

The Binder, Index Tabs, and all 100 accounts published to 1970 cost $18.00 to individuals, $20.00 to institutions. Subscription to the 25 accounts to be published in 1971 is an additional $5 for individuals, $7 for institutions.

Amer. Mus. Nat. Hist.
New York, N.Y. 10024

CHANGES OF ADDRESS

Please inform us of your address changes as soon as possible. Each returned copy of HERPETOLOGICAL REVIEW costs us (and you) about 25 cents more in postage and considerably more in handling.

Send address changes directly to:

HERPETOLOGICAL REVIEW
Genera of Reptiles Project
American Museum of Natural History
New York, N.Y. 10024

We will see that changes go to the mailing lists of SSAR, Herpetologists' League, and CATALOGUE, as well.

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be type-written on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $23.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/8 inches (one column) or 9 1/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 12 3/4 inches). Line cuts are reduced about 25 per cent in processing. [See also the special instructions for "Un-reviewed."]

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

UNREVIEWED-UNEDITED COMMUNICATIONS

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions. Drawings should be made to widths of 3 1/2" (one column), 7 1/4" (two columns), or 11" (three columns). Each vertical inch of drawing takes up six lines of text. The three-column format allows about 270 four- to five-word lines (35 characters and spaces) per page.

Page charges are: $20 for a single page; $40 for the two-page maximum. Include an allowance for the title and author's name and five lines for the address and received date. Send a check for the proper amount with the manuscript. Or, if you prefer, we will bill you that amount for reprints.

herpetological REVIEW

THE NEWSLETTER ON AMPHIBIANS AND REPTILES...
AND THE PEOPLE WHO STUDY THEM

VOLUME 3, NUMBER 5
OCTOBER 1971

S S A R

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

The SSAR encourages the acquisition of knowledge on amphibians and reptiles, and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communications between amateur and professional workers.

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society; they receive the JOURNAL OF HERPETOLOGY, HERPETOLOGICAL REVIEW, and issues of the Facsimile Reprint Series. They also receive reductions on the price of other Society publications. See the last page of this issue for information on membership and subscriptions.

HERPETOLOGISTS' LEAGUE

The Herpetologists' League is an international organization established by Major Chapman Grant in 1936. It is dedicated to furthering knowledge of the biology of amphibians and reptiles.

In 1970 it had 940 members and fellows, 24 life members, 10 honorary members, and 400 institutional subscriptions to its journal, HERPETOLOGICA.

All persons interested in herpetology are eligible for membership. Members receive HERPETOLOGICA (and now HERPETOLOGICAL REVIEW), to which they can submit manuscripts for publication. They may also present papers at the Annual Meeting.

See the last page of this issue for information on membership and subscriptions.

LETTERS TO THE EDITOR

ON THE AMBYSTOMA EGG-ALGA RELATIONSHIP

The unreviewed-unedited paper by Anderson, Hassinger and Dalrymple on "The egg-alga relationship in Ambystoma t. tigrinum" (1971 HERPETOL REV 3(4): 76) should be commended for its heuristic intent, but calls for some criticism of the methods and conclusions.

The more rapid rate of development, greater viability, and higher survival rate of eggs of Ambystoma maculatum reported by Gilbert 1942. ECOLOGY 22(2): 215-227; 1944. ECOLOGY 25(3): 366-369) were later confirmed by Hutchison and Hammen (1958. BIOL BULL 115(3): 483-489). In the 1958 paper we showed that the symbiotic relationship was not due to respiratory gas exchange and suggested that the higher metabolic rates and more rapid development of embryos associated with the alga must depend on some growth factor produced by the alga. In a later paper (Hammen and Hutchison. 1962. LIFE SCI 10: 527-532) we reported the results of studies with C-14 on carbon dioxide assimilation and showed that the "facultative mutualism of Ambystoma embryos and the alga Oophila is not simply one of photosynthetic carbon dioxide fixation by the alga with subsequent transport of labeled carbohydrate to the embryo". We concluded "that this physiological mutualism involves some growth factor produced by the alga in relatively small concentrations."

Anderson et al noted the occurrence of the alga only by visual observation. The alga is often present in eggs in considerable numbers without being apparent to the unaided eye; microscopic examination of the egg is necessary to determine actual occurrence. The increase in frequency of algal infestation with season observed by Anderson et al may have been due to an increase of algal density to a degree visible to the naked eye. I have found upon microscopic examination that the alga is often present during gastrulation, although it is not visible to the unaided eye, and that almost invariably, the density of the alga increases until hatching. If the egg-alga relationship is due to some growth factor produced in minute amounts as our earlier work suggests, then an algal density not sufficient to be seen with the naked eye could still be adequate to enhance egg development and survival.

The juxtaposition within the same sentence of the statements by Anderson et al that they found no beneficial effects of the alga and that they "in fact found a consistent correlation of the alga with higher mortality" might lead an unwary reader to conclude that the death of the embryos was caused by the alga. There is no evidence whatsoever that this is the case. The density of alga cells does increase greatly within the egg envelopes after the embryo dies, not before.

The earlier investigations under controlled laboratory conditions in pond water have shown that the alga does benefit the embryo; Anderson et al offer no valid data to show that this relationship does not also hold under field conditions. I agree that workers should note the occurrence of the alga in egg masses in the field, but only after microscopic examination. Temperatures are also important, but should be taken within the egg masses since the temperature of the masses often may be appreciably higher than the surrounding water. The amount of light reaching the eggs at different times of the day and season is also of importance in influencing the growth of the alga and should be measured and compared.

POLL OF HERPETOLOGISTS

IF YOU HAVE NOT YET FILLED IN THE POLL FORM (H R 3(3): T58, June 1971), PLEASE DO SO NOW AND SEND IT IN!

The Joint Committee on Cooperation needs additional information on the wishes of the membership before its next meeting in December. Only 148 replies were available at the August meeting, and only 195 have arrived to date (11 September).

THE PHILADELPHIA HERPETOLOGICAL SOCIETY

INVITATION TO THE

EAST COAST HERPETOLOGICAL SOCIETIES JOINT MEETING

Tuesday,

December 28, 1971

AT THE

PHILADELPHIA ZOO'S NEW REPTILE HOUSE

Participating Societies

Philadelphia Herpetological Society
Virginia Herpetological Society
Northern Virginia Herpetological Society
Maryland Herpetological Society
Connecticut Herpetological Society
New York Herpetological Society

On December 28 and 29, 1971, the Herpetologists' League, together with the Society for the Study of Amphibians and Reptiles will be holding their annual sessions in Philadelphia.

We are joining in with these professional organizations at this time and have set up a meeting for the morning of December 28. We will gather at the new Reptile House on the grounds of the Philadelphia Zoo at 34th Street and Girard Avenue at 10:00 o'clock A. M. There will be remarks from the officers of the societies present and then Dr. Roger Conant will take us on a tour of this most modern reptile facility.

Following that, Philadelphia Herpetological Society will provide a buffet lunch and will then go to the Benjamin Franklin Hotel where the two professional societies will have a session for the presentation of scientific papers.

Come to Philadelphia on December 28, 1971, for a day which may well prove to be the beginning of a new era of cooperation between the professional and the amateur or regional herpetological groups.

REPORT FROM THE JOINT COMMITTEE FOR COOPERATION OF THE HERPETOLOGISTS LEAGUE AND SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Executive Council of HL and the Board of Directors of SSAR approved the formation of a joint committee during the AAAS meetings in Chicago in December, 1970. The appointed members met for the first time in Chicago and again during the SSAR meetings at Albuquerque in August, 1971. During the intervening period a large volume of correspondence was transmitted between members of the Committee and with other interested persons.

The Committee has explored ways for increasing cooperation between the two herpetological societies to achieve greater benefits for the members of each organization. The current joint support of Herpetological Review and co-sponsored meetings in Albuquerque and Philadelphia are evidences of increasing cooperation.

The most conclusive form of cooperation, of course, would be amalgamation of these societies into one new organization. Such a move, with all of the attendant problems, has been discussed by the Committee. The primary concern in the considerations has been provision of the most services possible for the "membership dollar," and the effects of unification on present and future services to the membership are being studied in detail. Therefore, before this Committee can make a recommendation on amalgamation, the financial details must be fully analyzed. Since the financial status of both organizations for the current year will not be clear until December, the committee hopes to make a recommendation on the feasibility of amalgamation after a meeting in Philadelphia during the last week of December. If unification is recommended, the Committee will also present a Constitution and By-laws for the new organization, and a timetable for accomplishing the change.

The voting membership of both societies must approve any proposed change, in accordance with present constitutional requirements.

Should the Committee not recommend amalgamation, or if amalgamation were recommended but not approved by the members of both societies, the Committee would continue to study other joint activities of potential benefit to the herpetological community. The Committee earnestly solicits opinions or suggestions concerning any phase of cooperative activity, including amalgamation, from the members of HL and SSAR; comments may be sent to Victor H. Hutchison, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73069.

The Committee is composed of Kraig Adler, Herndon G. Dowling, Robert E. Gordon, Hobart F. Landreth, Clarence J. McCoy, Henri C. Seibert (represented by Ronald Brandon at Albuquerque), Wilmer W. Tanner, and Victor H. Hutchison (Chairman).

HERPETOLOGICAL PAPERS PRESENTED AT THE FIFTH LATIN AMERICAN CONGRESS OF ZOOLOGY IN MONTEVIDEO, URUGUAY

October 18 - 23, 1971

[C. J. McCoy, Carnegie Museum, attended these sessions, and kindly provided these translated abstracts. - Ed.]

ACHAVAL, FEDERICO (Facultad de Humanidades y Ciencias, Montevideo, Uruguay). The genus Clelia in Uruguay.

The author presents descriptions and synonymies, and notes on coloration and distribution of Clelia occipitolutea and C. rustica, based on specimens in Uruguayan collections.

BARRIO, A. (Instituto Nactional de Microbiologia "Carlos G. Malbran", Buenos Aires, Argentina), F. A. SAEZ and PRIMAROSA RINALDI CHIERI (Instituto de Investigacion de Ciencias Biologicas, Montevideo, Uruguay. Cytogenetics of Chthonerpeton indistinctum (Gymnophiona: Typhlonectidae).

A cytogenetic study of Chthonerpeton indistinctum, an amphibian of the order Gymnophiona, is presented. The diploid number of chromosomes in both sexes is 2n=20. The karyotype consists of five pairs of metacentric chromosomes, four pairs of submetacentric chromosomes, and one pair of telocentric chromosomes. Meiotic behavior reveals the presence of annular bivalents and non-terminal chiasmata similar to those of urodeles, and the existence of a major spiral approaching that of anurans. The low number of chromosomes and absence of microchromosomes, united with biological and anatomical characters, brings us to the conclusion that C. indistinctum is a species phylogenetically advanced over I. glutinosus and U. narayani, at this time the only other apodans studied from the point of view of cytogenetics. Morphologically differentiated sex chromosomes, such as occur in the other orders of amphibians, were absent in all meiotic preparations.

BLAIR, W. FRANK (University of Texas, Austin, Texas, U.S.A.). Some aspects of evolution in the genus Bufo.

Abstract not available.

BRUM DE ZORRILLA, NADIR and WALDO VENEGAS (Instituto de Investigacion de Ciencias Biologicas, Montevideo, Uruguay). Rapid technique for study of somatic and meiotic chromosomes in amphibians.

A rapid technique for study of somatic and meiotic chromosomes in anuran amphibians is described. By means of the action of collagenase on the connective tissue and collagen fibers surrounding the seminiferous tubules it is possible to obtain a good cellular dispersion which facilitates immediate observation of chromosomes in different stages of the meiotic process.

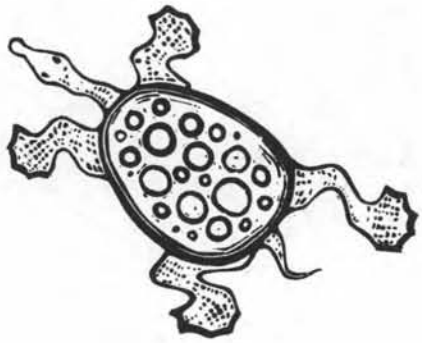
DONOSO-BARROS, ROBERTO (Universidad de Concepcion, Chile). Agressive behavior in Calyptocephalella caudiverbera (Linnaeus).

Examples of the giant frog of Chile upon being stimulated, and at times spontaneously, exhibit behavior reminiscent of the ceratophridian frogs. Individuals raise themselves on extended legs and move laterally, emitting strong agressive calls and attempting to bite. This behavior is found in adult males and females, and in transforming individuals. Sonographic study reveals a typical agressive call similar to that of the ceratophridians.

DONOSO-BARROS, ROBERTO (Universidad de Concepcion, Chile). Contribution to knowledge of the genus Aruncus Philippi.

This genus, described by Philippi at the beginning of the century (1902), was revealed clearly through the plates published by Cei (1958). The type-species of the genus is Aruncus valdivianus Philippi, and despite some differences attributable to technical difficulties of the early naturalist, the description is identifiable with material extant in the collection of the Universidad Austral. Therefore it is convenient to re-establish the name Aruncus valdivianus for the species known as Telmatobufo australis. A second related species is Telmatobufo bullocki Schmidt, the type-species of Telmatobufo. In searching for the type-specimens of Philippi I found the type-specimen of Bufo venustus, which is identical with Telmatobufo bullocki, resulting in bullocki becoming a synonym of Bufo venustus (=Aruncus venustus). In this latter species the middle ear is absent, as in Alsodes monticola, and its swimming strokes are very anomalous. The geographic distribution of Aruncus is extended from the province of Nuble to Malleco and Arauco in the Cordilleran Forest.

DONOSO-BARROS, ROBERTO (Universidad de Concepcion, Chile). The genera Ctenoblepharis and Phrynosaura.



These genera of lizards, described originally from the desert regions of northern Chile and Peru, have been considered distinct. The opportunity to review the type-specimen of Ctenoblepharis adspersus Tschudi in the collection of the Museum of Neuchatel (Switzerland), and the type-specimen of Phrynosaura reichei Werner in the Zoological Museum of the Universidad de Concepcion, permitted me to confirm the validity of both species, and to reach the conclusion that Ctenoblepharis Tschudi and Phrynosaura Werner are congeneric. Thus the genus of Werner, for reasons of priority, must be considered a synonym of Ctenoblepharis, the older name (1845).

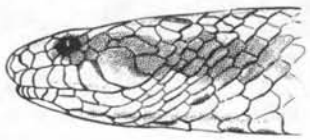
FABIAN, MARTA ELENA (Museu Rio-Grandense de Ciencias Naturais, Porto Alegre, Brasil). Contribution to knowledge of the cranial osteology of Liophis Wagler (Serpentes, Colubridae).

Osteological characters are of great importance in systematic studies of snakes. In view of this, differences in cranial osteology between the species Liophis anomalus (Guenther), Liophis jaegeri (Guenther), Liophis miliaris (Linnaeus), and Liophis occipitalis (Jan), are presented. The principal characters studied are numbers of maxillary, palatine, pterygoid, and mandibular teeth, length of the maxillary diastema, and proportions of supratemporal and quadrate bones.

FREIBERG, MARCOS A. (Buenos Aires, Argentina). Two new species of terrestrial tortoises (genus Geochelone) from Argentina.

Abstract not available.

GALLARDO, JOSE M. (Museo Argentino de Ciencias Naturales, Buenos Aires, Argentina). Origin of the South American amphibian fauna.



In considering this problem it is necessary to keep in mind the important role played in determining distribution by the interrelated factors of climate, topography, distribution of water bodies, soils, vegetation, feeding, reproductive behavior, and development. Given these data, three sources of origin can be recognized in the South American amphibian fauna. A) Guianan-Brazilian, reaching northward to Central America and southern United States and southward to northeastern Patagonia, containing the greatest number of species. B) Paleartic, represented by several species of Bufo (B. variegatus and related forms) from western South America. C) Patagonian (actually Andean-Patagonian), probably of Australian ancestry, with an appreciable number of species. The Guianan-Brazilian batrachofauna (the richest of the three) differentiated in certain refuges to the level of species or subspecies, and later dispersed radially and convergently through hydrographic systems (Bufo granulosus, Pseudis paradoxus, and others), a pattern of speciation also seen in certain mammals (Primates), birds, lizards, and some insects (Lepidoptera).

GARCIA, DANIEL (Museo Nacional de Historia Natural, Montevideo, Uruguay). Confirmation of the presence of Liophis occipitalis (Jan, 1863), in Uruguay.

The presence of Liophis occipitalis in Uruguay is confirmed by the acquisition of a specimen from the Department of Artigas. Previously the species was known from two specimens mentioned by Devincenzii (1925), one with only the data "Uruguay", and the other from the Department of Cerro Largo, constituting the first records for the country but remaining unverified until the present.

MANE-GARZON, FERNANDO and ORLANDO GIL (Facultad de Humanidades y Ciencias, Montevideo, Uruguay). Sessile papilloma of the gall bladder in a turtle from Uruguay, Phrynops geoffroyana (D. & B.).

Considering the extreme rarity of tumours in reptiles, especially in chelonians, a papilloma of the gall bladder found in a turtle from Uruguay, Phrynops geoffroyana (D. & B.) is described, including macroscopic and histological characteristics which identify it as a benign fibropapilloma.

OREJAS-MIRANDO, BRAULIO and DANIEL GARCIA (Museo Nacional de Historia Natural, Montevideo, Uruguay). Cyclagras gigas, a new species of snake (Serpentes, Colubridae) for Uruguay.

This species has been reported from an extensive area of tropical America, limited in the south by northern Argentina, Paraguay, Bolivia, and northeastern Brazil, and extending throughout northern South America, east of the Andes. Although the type-locality (Corrientes, Argentina) suggests the proximity of this species to Uruguay, the southernmost localities previously reported are those of Freiberg (1939) who studied specimens from La Paz and Parana, western Entre Rios, near the border of Santa Fe, Argentina. In 1959 a specimen of Cyclagras gigas (Dumeril, Bibron and Dumeril) was collected at Paso Pache, Department of Florida, Uruguay, and later donated to the National Museum of Natural History in Montevideo, where it bears number 1457. This specimen extends the known range of the species toward the southeastern part of South America.

SACCONE, ROBERTO (Luis B. Cavia 2745, Montevideo, Uruguay). List of vertebrates now extinct or with problems affecting populations in Uruguay.

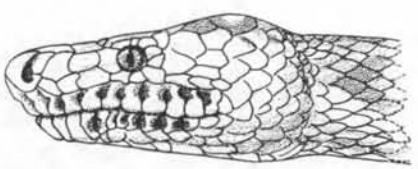
A list of birds, mammals, and reptiles is presented, with discussion of the general evolution of populations and the probable causes which resulted in or are resulting in the diminution of each species.

SAEZ, F. A. and W. VENEGAS (Instituto de Investigacion de Ciencias Biologicas,

Montevideo, Uruguay). Cytogenetics of Rhinoderma darwini (Amphibia, Anura).

A cytogenetic study of the anuran amphibian Rhinoderma darwini, the "sapito vaquero" of southern Chile, is presented. The karyotype consists of 2n=26 chromosomes which may be arranged according to relative size in six large pairs and five small pairs. Analysis of meiosis reveals distal chiasmata, from which is inferred restriction of crossing-over and a large degree of linkage, limiting recombination. Sex chromosomes were not found. Other work relating to systematics and the meiotic process is discussed.

STERN, CLAUDIO (Francisco Soca 1514, Montevideo, Uruguay). Chromatic variation with age in Lystrophis dorbignyi (Dumeril, Bibron and Dumeril, 1854) (Serpentes, Colubridae).



Chromatic variation with age was observed in a series of Lystrophis dorbignyi. In adults there appears, in the lateral black spots, a red coloration that is completely absent in juveniles. This red coloration occurs every 6 to 9 ventral scales, from the neck to the anal area. Since this chromatic variation does not correlate with ecological preference or with sex of the individuals, it must be considered ontogenetic variation.

VAZ-FERREIRA, RAUL and ANNELISE GEHRAU (Facultad de Humanidades y Ciencias, Montevideo, Uruguay). Aggregations and behavior of tadpoles of Leptodactylus ocellatus (L.).

Aggregations of tadpoles of Leptodactylus ocellatus (L.), forming groups of more than one thousand individuals, are found in temporary water bodies in Uruguay. These aggregations display compact form, moving at times through shallow areas. The tadpoles feed by rasping the surface of plant stems and detritus while the aggregation moves through certain areas of the pool. The aggregation modifies its aquatic environment by agitation and increasing the temperature. The survival value of this behavior in the freshwater community is discussed.

VAZ-FERREIRA, RAUL, LUCRECIA COVELO DE ZOLESSI and FEDERICO ACHAVAL (Facultad de Humanidades y Ciencias, Montevideo, Uruguay). Oviposition and development of snakes and lizards in anthills of Acromyrmex, II.

A previous contribution on this subject is complemented by additional information on new collections, and on characteristics of the eggs and hatchlings of the snakes and lizards that utilize anthills of Acromyrmex as incubation chambers. The authors list new localities and situations in anthills for Philodryas patagoniensis (Girard), Liophis obtusus (Cope), Micrurus frontalis altirostris (Cope), Pseudablabes agassizi (Jan), Clelia rustica (Cope), and Teius teyou (Daudin), and note other species with this same behavior. The behavior of hatchlings is described, and further information is presented on the ecological character of the fungus chambers of Acromyrmex.

CONSERVATION PAGE: TURTLES CATCH IT FROM SEVERAL DIRECTIONS

Arising from concern over the decrease in the numbers of amphibians and reptiles in Britain, the BRITISH HERPETOLOGICAL SOCIETY has set up a Conservation Committee. This committee will bring together as much information as possible on the important remaining habitats for amphibians and reptiles in Britain. Every effort can then be made to protect as many as possible of these sites to ensure the survival of these interesting groups of animals.

This work will be carried out in cooperation with the Nature Conservancy and County Conservation or Naturalists' Trusts. The committee will also be pleased to give advice to interested parties on any matter relating to conservation of amphibians and reptiles. Anyone interested and prepared to help the committee in its work should get in touch with the Chairman: Mr. M. R. K. Lambert, the British Herpetological Society, c/o Zoological Society of London, Regent's Park, London, NW1 4RY. (From HABITAT 7(6)).

Turtles in Soup Over Salmonella

Pet Turtles Will Be Banned in N.J.

INTERNATIONAL TURTLE & TORTOISE SOCIETY, Inc.
8847 DE HAVILAND AVENUE • LOS ANGELES, CALIFORNIA 90045 • P.O. BOX 45555 • PHONES: FR 5-0873 • 645-7351

MEMBERS: Send in Salmonella Reports!

SUBJECT: Our Privilege to Keep Pets!

The case of turtles and *Salmonella* infection continues to make headlines and news notes. I.T.T.S. staff is seeking authentic reports and studies on this controversial issue.

We feel that turtles are being unjustly singled out as sources of this rarely-fatal infection. The case against them continues to be made – based on the findings of tests on scattered specimens – seemingly on the premise that: "Well, your parrot doesn't seem to carry *Salmonella*, so it must be from your turtle." (This was reported to the editors by a member who had an ear infection. There was no attempt to test either bird or turtle!)

If we value our right and privilege to keep pets, we must sort out fact from fiction and hearsay, truth from untruth or surmises on this question. Admittedly, improperly kept and cared for turtles may be a source, but documentation also includes as sources: cats, dogs, birds, swine, fish, lizards, insects, rats, mice, chameleons; meats, candy bars, eggs, powdered dry milk, deviled egg-and-shrimp (sandwich combination), animal by-products used in animal foods, and fertilizers. Food-slicing machines and unwashed human hands have also been known to be carriers.

The state of Washington now bans turtles until they have favorably passed examination. Why are not all other members of the animal kingdom so tested?

Today: Washington! Tomorrow: the world? Let's not sit idly by until it is too late and another personal freedom is made the subject of unwieldy and unjustified legislation!

Sincerely yours,

The Editors

Medifacts

New developments in medicine that may affect your health

TURTLE-BORNE SALMONELLA Hartford, Connecticut, epidemiologist Dr. Steven H. Lamm has just completed a study, reported in *Medical World News*, that shows that pet turtles are a far more frequent cause of salmonella infections than was formerly supposed. In fact, if Connecticut is representative of the rest of the country, about one fifth of an estimated two million salmonella infections each year are contracted from turtles.

After detailed investigation of illness in sixty-six families implicated turtles in 27 percent of the cases, Dr. Lamm undertook a field investigation of the source of the bacteria. He and Mr. Arthur Bruce of the state laboratory made cultures from the turtle tanks of all eighteen pet stores in Bridgeport, Meriden and Bristol and found that every one contained salmonella. However, the pet dealers themselves were not at fault. Further study proved that the turtles were already contaminated when they were received from the supplier; and a visit to one supplier, a turtle farm in Louisiana, showed conclusively that poor conditions there were the original source of infection. As a solution, Dr. Lamm proposes Federal regulation of commerce in turtles. In the meantime, parents would do well to remember that turtles are not necessarily the cheap, simple pet they seem to be. In eight of the Connecticut cases, the disease they carried was severe enough to require an average of eleven days hospitalization at a cost of $1,200 per child. (WOMEN'S DAY, September 1971)

RADIATED TORTOISE OWNERS.
A group of concerned collectors is taking a census of all Geochelone radiata in the country for the purpose of exchanging ideas on the care, feeding, and captive reproduction of the species. Possibility of a periodic newsletter being started to keep all owners abreast of new developments and ideas for captive breeding, etc. Your cooperation is urgently needed. If you own a radiated or know someone who does, please contact: William H. Zovickian, 1200 Burnham St., Colorado Springs CO 80906.

TURTLES ON THE MOVE.
California Fish and Game has authorized the California Turtle & Tortoise Club to relocate 30 or 35 tortoises (Gopherus agassizii) from California City to the Lancaster area.

CONSERVATION CREDO.
Dreamed up by wildlife lovers and campers: "Take nothing but pictures, leave nothing but footprints." (From TORTUGA GAZETTE 7(9):4.)

REGIONAL SOCIETIES PAGE

NEW SPONSOR FOR ENGELHARDTIA.
Engelhardtia is now published by the Long Island Naturalist Society. Prior to 25 March 1971, this group was known as the Long Island Herpetological and Ornithological Society. The journal (my last issue is vol. 4 no. 2) increasingly reflects the group's devotion to the natural history of Long Island and nearby regions. Its pages also contain notes on the field trips sponsored by the society. Meetings are held at the Nassau County Museum of Natural History (Seaford, Long Island).
For an additional $4.00 one can join the JAMAICA BAY CHAPTER of the Long Island Naturalist Society in the region of New York City.

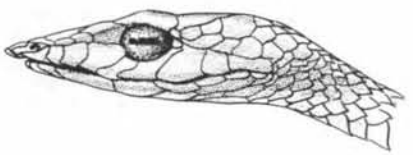
BOB DUBOS (past treasurer of Connecticut Herpetological Society) is a member of the scientific study team in the Aleutian Islands.

SUE SLATE (U. Conn.) has begun a definitive search for reptiles and amphibians in Litchfield Co., Conn.

EASTERN SEABOARD HERPETOLOGICAL SOCIETIES.
Staten Island Zoo, on October 9th, will be the scene of the combined meeting.

NEW SOCIETY IN INDIANA.
Indiana Herpetological Society (c/o Garry S. Bryan, 453 N. Grant St., Martinsville IN 46151) is being formed.

MASSACHUSSETTS (NEW ENGLAND AREA).
A new Turtle & Tortoise Society is starting here (John C. Stuart, 47 Garrison Rd., Brookline MA 02146). This will be primarily devoted to the protection and conservation of the turtles of that area.



WELCOME: INLAND EMPIRE BRANCH.
The Southwestern Herpetologists Society has welcomed to its ranks a fourth branch, the Inland Empire, based near San Bernardino (c/o Dr. Joe Gorman, Dept. Biol., U. Redlands, Redlands CA). The group meets on the first Tuesday of each month, 7:30 p.m., at the San Bernardino County Museum, in Bloomington.

LODI CALIFORNIA AREA.
Get in touch with Mrs. Lillian Dickinson, 1507 W. Park St., Lodi CA 95240. She has just recently held a turtle/tortoise display at the Lodi library with the idea of getting interested people together to form a Turtle & Tortoise Club there.

OJAI CALIFORNIA AREA.
Here get in touch with Mrs. Lillian Greene, Rt. 3, 130 N. Lomita, Ojai CA 93023. She and a few more people in her area are looking for enough people to start a Turtle & Tortoise Club, too.

NEW JOURNAL

HISS just received the recent issues of NOTIZIARIO DELLA UNIONE ERPETOLOGICA ITALIANA, published by the Unione Erpetologica Italiana (Museo Civico di Zoologia, 00197 Roma, Via Ulisse Aldrovandi, 18 Italy). The 52 mimeographed pages of the 2 issues of Volume One contain articles by Silvio Bruno, Giuseppe Maria Carpaneto, Lucia Naviglio, Guy Naulleau and reports, reviews, meetings and lectures, Italian herpetological literature and conservation. The cartoon and illustrations were drawn by Stefano Maugeri. Membership dues for 1971 include the journal subscription. Regular L.1500, Student L.1000, Supporting L.5000.

ANOTHER SOCIETY?

It was a pleasant surprise to receive the first issue of BULLETIN DE LIAISON DU GROUPE DE TRAVAIL SUR LES AMPHIBIENS D'AFRIQUE. In addition to Arne Schiotz "Preliminary report on a collecting tour to East Africa" it also contains a "List of herpetologists working on African Amphibia". Abstracts of the first meeting (27-29 Nov. 1969) are presented. Attending the meetings were A.G.C. Grandison (Britain), Mills Tandy (USA), G.F. de Witte and S. Orts (Belgium), F. Xavier, J. Guibe, L.P. Knoepffler, M. Lamotte (France), A. Schiotz (Denmark), J.L. Perret (Switzerland) and K. Klemmer (Germany).

GEOGRAPHIC DISTRIBUTION PAGE

We announced some time ago that HERPETOLOGICAL REVIEW would publish brief notices of new geographic records, in order to make these available to workers in published form. The STANDARD FORMAT for these records is:

SCIENTIFIC NAME. Locality; Date; Collector. Identified or verified by. Place of deposition and catalogue number. Comments. SUBMITTED BY, and address.

Please submit new locality records to: GEORGE R. ZUG, Division of Reptiles & Amphibians, National Museum of Natural History, Washington, DC 20560.

CURRENT HERPETOLOGICAL TITLES, XVII: 1970 - 1971

Herpetological Information Search Systems
American Museum of Natural History
New York, New York 10024

We have brought to your attention more than 13,000 current titles in the pages of this journal to date.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any current paper (e.g., 1970-1971) that is concerned with a member of a Recent order of amphibians or reptiles.

HERPETOLOGICAL REVIEW has appeared bimonthly, beginning in 1971. This means that the titles published here will be even more current. We hope that the added numbers will serve to reduce the titles-per-issue to a more manageable number.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This list contains titles of books and articles that have come to our attention during the period 22 May through 16 July 1971. Periodical title abbreviations follow the American Standard for Periodical Title Abbreviations Z 39.5-1963 (American National Standards Institute, Inc., New York).

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and L. Greene. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. The library staff of the Museum have continued to aid our project. Special thanks to the members of the Herpetology Department, AMNH for their aid in cross indexing, which allows us to offer new services. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

No commercial computer service yet offers all of the facilities that we need and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 35 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

NEW H I S S SERVICE

BESIDES the "Current Herpetological Titles" section that appears regularly in HERPETOLOGICAL REVIEW, for some years HISS has been producing these same titles on sets of library cards for about ten institutions. These have appeared quarterly, and are arranged alphabetically by author.

Beginning in 1972, HISS will amplify this service by providing four differently-arranged card decks, and by supplying them in two different formats (about 1,000 cards per quarter):

DECK 1. Arranged alphabetically by AUTHOR; 25-35% with abstracts.
DECK 2. Arranged by SUBJECT (e.g., ecology; embryology; physiology; taxonomy); sorted to the smallest inclusive term.
DECK 3. Arranged by TAXON (e.g., Rana; Reptilia; Hylidae); sorted to the smallest inclusive taxon (to species).
DECK 4. Arranged by GEOGRAPHY (e.g., Ghana; Alabama; Oriental Region); sorted to the smallest inclusive term (to country or state).

As indicated, about 30% of the cards in Deck 1 will have abstracts. In addition, all of the cards will bear a code-line that indicates its allocation in all three categories: subject, taxonomy, and geography.

All of the above will be produced on Library of Congress stock, punched and cut to standard library (approximately 3x5") dimensions.

They also will be produced on pages of 90-pound ledger stock, un-punched and uncut, but marked for cutting. This method of production reduces the cost to about half -- thus bringing the cost of an entire deck to within the price-range of an interested individual.

Furthermore, we will sell parts of the indexed decks (90-pound stock) at a fraction of the cost of the entire bibliography. By selecting a restricted area of interest (e.g., anatomy; Plethodon; Texas), an individual can receive quarterly notice of papers in his field some 10 to 30 months before such notice would appear in BIOLOGICAL ABSTRACTS or ZOOLOGICAL RECORD ("Amphibia" or "Reptilia" not accepted).

ANNUAL SUBSCRIPTIONS ARE:

	INDIVIDUALS	INSTITUTIONS
AREA ALERTING SERVICE:*		
First subject-area.....	$25.00	$50.00
Additional subject-areas (each)**.....	20.00	40.00
ANNUAL BIBLIOGRAPHY OF HERPETOLOGY		
On Library of Congress stock, cut & punched		
Deck 1.....	150.00	250.00
Decks 2-4.....	100.00	200.00
On 90-pound pages of ledger stock, marked for cutting (per deck).	75.00	150.00

* Retrospective searches (1758-present) cost about ten times the annual rate.
** Because all codes are hierarchial, the terms for any broad unit also includes any more restricted terms within it (e.g., Ethiopian region includes references to Kenya; Caudata includes Triturus).

1971 herpetologists' YEARBOOK

WITH A CALENDAR FOR 1972

PREPARED BY

The Genera of Reptiles Project
Department of Herpetology
The American Museum of Natural History
New York, N. Y. 10024

$15.00

- A "Current" section will include a Calendar for Herpetologists, information on college courses in herpetology, sketches of herpetological societies and herpetological collections, the status of endangered amphibians and reptiles, and perhaps of greatest interest, a Directory of Living Herpetologists.
- A major section will present basic information on amphibians and reptiles: classification, longevity, critical temperatures, fecundity, and sizes. An up-to-date Checklist of the species of amphibians and reptiles in the United States and Canada will be included -- the first since K.P. Schmidt's in 1953.
- Some outstanding portraits of amphibians and reptiles will be presented.
- An entire section will be devoted to venomous snakes and the problems associated with them: snakebite, antivenins, and a discussion of snakebite treatment.
- Special review articles will summarize the current knowledge of amphibian and reptile chromosomes, will present a taxonomic arrangement of North American snakes, and reviews of other subjects.
- American Standard abbreviations for more than 1,000 journals that publish information on amphibians and reptiles will be given.
- And each of these sections will be indexed thoroughly and fully referenced.

The HERPETOLOGISTS' YEARBOOK for 1971 is in preparation and will be issued in the fall of this year. The Yearbook is a new idea in the field. Besides reviewing the status of special subjects on amphibians and reptiles, it will provide basic data on the biology and classification of these animals. This information, culled from the material retrieved and consolidated by the Genera of Reptiles Project (HISS) at the American Museum of Natural History, will be consulted on almost a daily basis by anyone who is interested in amphibians and reptiles. This first annual issue will contain hundreds of important items of information on these animals. We expect future issues to grow into a regular almanac of herpetology.

HEMIPENIAL MORPHOLOGY OF THE TREE LIZARD, PLICA PLICA (LINNAEUS)

H.G. Dowling, T.C. Majupuria, & F.W. Gibson

The structure of the male genitalia of lizards has been little studied and its possible taxonomic significance has not yet been assayed. Cope (1896) was the first to survey the variation in hemipenial structure. He suggested that it had considerable taxonomic importance, but he only briefly described the hemipenes of a few representative species of lizards from several families, and did not follow up the results of this preliminary survey. Uzzell in his work on microteiids (1965, et seq.) is the only recent worker to utilize hemipenial descriptions as a major feature of his generic definitions.

The thin-walled structure of most lizard hemipenes and their small size (as compared with those of snakes) discourages their study as inverted organs. Their features of ornamentation consist mainly of calyces, flounces, ridges, and "welts," which must be inflated in the everted organ to be properly observed. However, in spite of Smith's (1946: 14) statement to the contrary, spinose hemipenes are found in some species (Uzzell, 1965: 82). However, the spines are small and inconspicuous in most and have been found to be only of seasonal appearance in Lacerta (Boehme, 1971). The apparent length of the organ in Sceloporus has been found to vary seasonally as well (Altland, 1943) and the absence of regularly-arranged subcaudal scutes in lizards makes size-comparisons between different genera difficult.

In spite of these difficulties of study, we believe that the hemipenes may give important information on the taxonomic relations of lizards, and look on this as the first of a series of papers in which we will investigate the value of hemipenial structure as a taxonomic character in the Sauria.

Aside from Cope's (1896) basic work, there are descriptions of the hemipenial structure of individual species from several workers. Among these are descriptions of Lacerta (Woepke, 1931), Hemidactylus, Calotes, Chamaeleon, and Mabuya (McCann, 1946), Uromastix hardwickii (Das, 1960), Anguis (Raynaud and Pieau, 1969), Brookesia (Brygoo & Domergue, 1969), and further studies on Uromastix hardwickii (Majupuria, 1969, 1970). Among these only McCann, and Brygoo and Domergue, attempted to attach taxonomic importance to the hemipenial structures described.

Attempts to correlate information on hemipenial structure also suffer from the lack of an adequate system of standardized terminology for use in the description of these organs. We hope to develop a system in the progress of these studies, which will be comparable to that for snakes that was given by Dowling and Savage (1960).

Cope (1896) gave brief descriptions of the hemipenis in a few species of iguanid lizards, but aside from some general remarks by a few other workers, the Family Iguanidae appears to have escaped study. Because this is a large and complex American family, with many specimens readily available, it appears to be an ideal base from which to initiate a comparative study of lizard hemipenes. The hemipenis of the well-known Neotropical tree lizard Plica plica is described here. Future studies will investigate intrageneric variation in polytypic genera, intergeneric variation, and test the reality of apparent familial characters of this organ.

THE HEMIPENIS OF PLICA PLICA

The following description is derived from the study of two pairs of hemipenes: both everted in one individual (HGD-796; Trinidad), the right everted and the left inverted in the other (AMNH 107590; Peru).

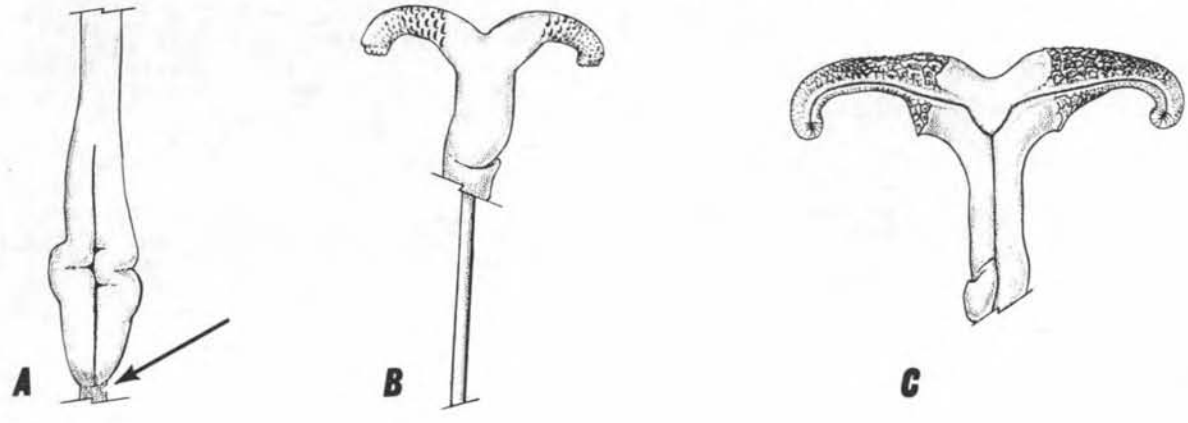

FIG. 1. Hemipenis of Plica plica: A. Inverted organ, showing attachment of muscle retractor penis (arrow) and slight compression of lobes in situ. B. Asulcate (= lateral) view of hemipenis, showing restriction of calyculate areas to apical lobes, basal fold, and the length of m. retractor penis (which originates on the fifth caudal vertebra) when organ is everted. C. Sulcate (= medial) view, showing course of sulcus spermaticus and distribution of calyculate areas.

Both preparations were done from fresh material. The latter specimen is an adult male with a snout-vent length of 105 mm (total length, 193 mm).

The hemipenis (AMNH 107590) has a total length of 15 mm in both inverted and everted conditions. In the inverted condition it lies under the feebly-developed muscle vaginalis penis, but toward the lateral edges of the tail. It is covered by an outer sheath which is almost transparent. A small medial slit in the sheath exposes the hemipenis and shows that the apical lobes in the inverted condition are situated distally with little compression (Fig. 1A). The muscle retractor penis originates on the fifth caudal vertebra. It passes forward between the ischiocaudalis and caudoilliofemoralis muscles, and inserts in two rami at the tips of the lobes.

The everted specimens (Fig. 1B) show the organ to be deeply bilobate, with each of the lobes being nearly the length of the subcylindrical basal stalk. An apparent difference in the length of the two lobes may be an artifact of preparation.

The sulcus spermaticus originates near the opening of the ductus deferens at a small depression in the upper wall of the cloaca. It extends through the cloacal aperture and along the basal pedicil of the hemipenis to near the level of the lobes. It bifurcates at this point and extends out on the medial side of the lobes to their apices (Fig. 1C). Its U-shaped channel probably is closed by the sulcus lips during copulation, thus serving as a tube to carry the semen from the urogenital opening in the cloaca of the male to near the oviducal opening in the cloaca of the female, without contamination from the excretory and fecal materials that also enter this region.

The pedicil of the hemipenis is smooth, without obvious ornamentation. There are two basal folds near its proximal end. The lobes are ornamented with reticulate patches of small, smooth-edged calyces, which extend from near the base of each branch to near the apex. These calyculate areas completely surround the apical lobes. Proximal to the calyculate areas, the bases of the lobes are relatively smooth.

The restriction of ornamentation to the apical lobes of the organ is notable, as is its presence completely around these lobes. Other features worthy of special note may appear with our continuing studies on the hemipenes of other lizards.

ACKNOWLEDGMENTS & ABBREVIATIONS

We thank Charles W. Myers and Richard G. Zweifel, American Museum of Natural History (AMNH), for their comments on the paper. We also thank Dr. Zweifel for providing space and facilities. Especial thanks is due Robert G. Goelet, President of the New York Zoological Society, for making possible Majupuria's stay in the United States.

Some of the specimens are in the private collection of H. G. Dowling (HGD).

EFFECTS OF DIFFERENTIAL PRESERVATION ON DERMAL PUSTULARITY OF THE MICROHYLID FROGS GASTROPHRYNE AND HYPOPACHUS

Craig E. Nelson

The extent of dermal pustularity in various North American microhylid frogs has occasionally been used as a taxonomic character (Dumeril and Bibron, 1841; Strecker, 1908; Stuart, 1963; and others). In a recent example, Stuart (1963), used the degree of pustularity as a principal character in separating some Guatemalan species of Hypopachus, contrasting them: "skin smooth though often covered with tiny spicules," "pustules frequently restricted to the posterior part of dorsum or confined to upper surface of thighs," and "dorsum and upper surface of thighs very pustular."

Although the extent of pustularity varies between live individuals within the same population for at least some species of North American microhylids (Burt, 1938, for G. olivacea and H. cuneus; Wright and Wright, 1949, for G. carolinensis; and personal observation for various species of Hypopachus), there are often distinct differences between series of both live and preserved microhylids in the extent of pustularity and its use as a taxonomic character in this group appeared well founded. However, Mertens (1952) reports a series of Hypopachus from a single locality in which one specimen was preserved apart from the bulk of the series and was subsequently observed to be distinctly more pustular than the others. He suggests that variations in preservative strength affect the pustularity of specimens of this genus. I have accidentally acquired data supporting Mertens' suggestion.

As a routine field procedure, I usually kill amphibians in a saturated aqueous solution of cloretone, inject them with 10 per cent formalin, harden them between layers of paper towels dampened with 10 per cent formalin, and fix them further in a jar of the same solution. In the course of interspecific hydridization, a few male microhylids were treated differently. These were killed by cutting through the back of the skull and the brain with a pair of scissors, the body cavity was opened and the testes were removed, and the carcasses were immersed in a jar of approximately 20 per cent formalin usually used for the preservation of specimens found dead on the road. In at least some cases, the carcasses showed considerable reflex action after immersion in the formalin. Specimens fixed by both procedures were subsequently stored temporarily in 10 per cent formalin, washed, and transferred for permanent storage to 50 per cent isopropanol. Several months later, when the specimens were studied, those which had been used in hybridization were almost all very pustular whereas almost all of those preserved by the standard procedure were smooth. In some cases, individuals corresponding to Stuart's most divergent classes (Fig. 1) were thus obtained from a series of specimens of one species collected from a single population. Specifically, a series of Gastrophryne usta from two closely adjacent localities near El Treinta, Guerrero, Mexico, and series of Hypopachus from 7.9 miles southwest of Las Cruces, Chiapas, Mexico, and 1.3 miles west of Duenas, Sacatepequez, Guatemala, showed this contrast (the specimens were deposited in the Texas Natural History Collection). Moreover, the routine procedure produced series of smooth frogs from populations which Stuart (1963) characterizes as uniformly very pustular.

The pustularity of specimens preserved by divers technique is thus not an appropriate taxonomic character in microhylines.

Support from National Science Foundation Grant GB-6204 is gratefully acknowledged. My wife, Sharon, assisted in the field studies.

INFLUENCE OF TRAP COVER TYPE ON PITFALL TRAPPING OF LIZARDS

William S. Parker

One method of sampling lizard populations is with the use of pitfall traps described by Banta (1957), variations of which have been used in population studies of desert lizards (Jorgensen and Tanner, 1963; Bostic, 1965; Spoecker, 1967). Banta (1962) described some of the advantages and disadvantages encountered with these traps. However, the influence of trap cover type on lizard captures has not been examined.

Influence of trap cover type on lizard captures was tested using an alternating pattern of rock covers, masonite square covers, and no covers. A brief experiment with pitfall traps was conducted in August 1966 with 99 one-gallon cans at an area about one mile south of Guadalupe, Maricopa County, Arizona. Williams (1968) described the study area and methods followed.

Four lizard species were captured in sufficient numbers to permit Chi Square analysis (Table 1). All except Coleonyx variegatus were young-of-the-year. Using the 0.05 level of significance, captures of Cnemidophorus tigris were distributed in a non-random manner, with a majority in rock covered traps. No significant difference was indicated for the other three species, but captures of Uta stansburiana are suggestive of a difference in captures between covered and uncovered traps.

Although the pooled data indicate covered traps caught a significantly larger number of lizards, a test of heterogeneity implies that perhaps pooling data for the four species was not justifiable (Table 1). Each species probably responded in a different way to the three cover situations. Captures of Coleonyx and Uta show similarly greater numbers in covered traps, but those for Dipsosaurus exhibit a random distribution.

Although sample sizes were too small to permit firm conclusions on any of the species, the results indicate that a further study of this nature would be rewarding and that extreme care must be taken in using pitfall traps for lizard population studies. One cover type may be significantly more successful in capturing a particular lizard species, and consequently significantly influence the results obtained.

I am grateful to Stanley C. Williams who designed this study for scorpions and allowed me to use his traps, and to William S. Brown and Lionel G. Klikoff for comments on the manuscript.

THE TADPOLE OF RANA PILEATA

W. Ronald Heyer

During the Field Museum of Natural History Herpetological Expedition to Thailand in 1969, a number of tadpoles were collected at the Sakaerat Biological Station located 250 km NE of Bangkok. The collection forms the basis of a report on tadpole ecology (Heyer, in prep.). Certain species were collected for the first time as larvae and described (Heyer, 1971). Mr. Karl J. Frogner recently allowed me to examine a collection of larvae that he made at Sakaerat from June through August of 1968. In the Frogner collection, the larvae of Rana pileata represent a species not present in the 1969 collections and a species not previously described.

The purpose of this note is to describe the larva of Rana pileata, which will complete the descriptions of all larvae known from Sakaerat. The methods and style of description are the same as those used previously (Heyer, 1971). Specimens will be deposited at the Applied Scientific Research Corporation of Thailand, Bangkok, The Bernice P. Bishop Museum, Hawaii, and the Field Museum of Natural History, Chicago.

Description: Head and body oval; snout rounded; eyes dorsal; distance between nostrils about equal to interorbital distance; mouth subterminal; oral disk emarginate laterally, oral papillae in a single row laterally and ventrally, double ventrolaterally, interrupted anteriorly and posteriorly; denticle formula -----; beak well developed, serrate; spiracle sinistral, in the middle of the side of the body; anus dextral.

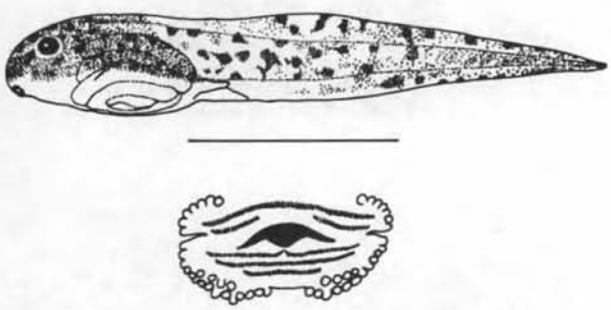

FIG. 1. Lateral view and mouthparts of tadpole of Rana pileata. Upper line equals 10 mm; lower line equals 1 mm.

Tail tapering to a point; dorsal fin beginning at end of body; greatest tail height usually less than body height.

Color pattern in preservative light brown flecked above, area around eyes lacking melanophores; no melanophores ventrally; tail spotted.

Eye moderately large, 9 to 13% head-body length; width of oral apparatus 17 to 21% head-body length; anterior papilla gap 50 to 67% oral apparatus width; head-body 32 to 38% total length; maximum total length recorded 38.9 mm at stage 40. (Fig. 1)

Ecological notes: Both adult and larval Rana pileata were collected along a seasonal stream, the Huai Pae, coursing through dry evergreen forest. Frogner (pers. comm.) collected the larvae from the bottoms of large pools in the stream bed. The pools were pond like in character, with little water movement through them. The larvae were lying on the bottom.

Relationships: Rana pileata belongs to a group of stream frogs whose larvae are not noticeably adapted for stream life, such as are those of the ranid genus Amolops. Larvae have been described for only three other species within this group: Rana blythii, R. kuhlii, and R. ibanorum (descriptions and figures of all three are in Inger, 1966). The dentition within the group seems unmodified, being a standard 2/3. With the three other known larvae, R. pileata shares the character of few, large oral papillae, which character, while not confined to larvae of this group, is not widespread throughout the genus. There is one character of oral apparatus morphology that supports Boulenger's (1920) species groupings. The known larvae of Boulenger's Grunnientes group have a posterior gap as well as an anterior gap in the oral papillae rows (R. blythii, ibanorum, pileata); while the known larva of the Kuhlianae group has but an anterior gap in the oral papillae (R. kuhlii). Rana pileata may be distinguished from blythii and ibanorum larvae by color pattern. R. pileata have large spots on the tail, R. ibanorum tails are not large-spotted; R. pileata do not have any melanophores ventrally around the mouth, R. blythii larvae have groups of melanophores sparsely grouped around the mouth.

ACKNOWLEDGMENTS

Karl J. Frogner (University of Chicago) kindly allowed me to examine his larval collection from Sakaerat and to prepare the description for Rana pileata. Robert F. Inger (Field Museum of Natural History) critically reviewed the note.

ARBOREAL HABITS OF BUFO VALLICEPS AND OTHER BUFONIDS

Jaime Villa

Tree-climbing Bufo valliceps were reported by Neill and Grubb (1971) from Reed Park (Austin, Texas). They found several individuals in trees and treeholes up to 5 m above the ground, witnessed their climbing ability and finally suggested that human disturbance in the area of study and "rapid seasonal changes in population size and composition in Reed Park" may help explain "this unusual phoenomenon".

In January 1966, during a 10-day stay in Great Corn Island, Caribbean Nicaragua, J. A. Roze, E. B. Seligmann, R. G. Zweifel, and myself observed that during the day many individuals of B. valliceps retreated into tree-holes, on branches, palm axils, and under abandoned termite nests up to 2.5 m above the ground. Although the island has its share of habitat disturbance, due to rather primitive coconut harvesting (which in this case provides the abundance of coconut husks toads use as shelters), most of the individuals found on trees were in the "mountainous" parts of the island where coconut harvesting is negligible.

In a second visit to the island on June 1969, well into the rainy season, several more B. valliceps were found in trees, although they seemed to be concentrated around breeding pools. Possible seasonal changes in size and composition of Corn Island B. valliceps remain to be detected.

In San Juan del Norte (Departamento de Rio San Juan), a Nicaraguan mainland locality, B. valliceps was not especially abundant in March 1971. Not more than two dozen individuals were seen in one night. Two adult B. valliceps were found 3 m above the ground among epiphytic vegetation. The area seemed notoriously undisturbed.

These observations suggest that arboreal habits in B. valliceps are (at least in the tropics) more common and widespread than previously thought and that they are not necessarily correlated with habitat destruction. Arboreal habits in Neotropical Bufo are not, in fact, restricted to B. valliceps. I have found B. luetkenii, a species apparently related to and often difficult to distinguish from B. valliceps, in trees in several undisturbed localities in Esteli, Managua, Somotillo, and Tipitapa (Nicaragua). Finally, Noble (1918) after collecting in eastern Nicaraguan localities (Maselina Creek, Kanawa and Cupitna Camp, Dept. of Zelaya), which seem as undisturbed today as they were 55 years ago, reported finding B. coniferus in three main habitats, one of which was "Moss-covered vine about five feet from the surface of the water in a forest swamp".

I am indebted to Mssrs. Neill and Grubb for critical reading of this note and further comments on their paper.

BEHAVIOR OF LIZARDS IN AN ARTIFICIAL SHADE MOSAIC

Kenneth K. Asplund

ABSTRACT: Behavior of whiptail lizards (Teiidae, Cnemidophorus) in an artificial mosaic of shade shows that lizards of relatively larger body size confine thermoregulatory cooling to larger pieces of shade than do smaller lizards. It seems that smaller lizards may, when thermally motivated, respond differently to visual cues, relative to larger lizards, during use of an environmental thermal mosaic.

Many closely related species of bisexual whiptail lizards (Teiidae, Cnemidophorus) inhabit the Sonoran Desert and adjacent regions. The larger forms are often restricted to the shadiest habitats (C. maximus in thorn scrub; C. burti stictogrammus in riparian canyons and foothills of middle elevation); related smaller forms are frequently common in open desert scrub and desert grassland communities (C. tigris; C. burti xanthonotus).

There may be several selective advantages of small body size in desert habitats. They relate generally to the relatively greater capability of smaller lizards to effect thermal exchange with the environment. Smaller lizards can have relatively earlier seasonal periods of activity; during cool periods they maintain their elevated eccritic temperatures more effectively than do larger lizards (Cowles, 1941). During hotter times of day and of the year, smaller lizards may cool more rapidly following exposure to high temperatues (Cole, 1943).

In arid habitats like subtropical deserts, diurnal reptiles are ordinarily restricted to the vicinity of shade, in part as a function of body size. Supposedly the smaller species can find shade, where larger species cannot, in the canopy provided by scattered desert shrubs (Cowles and Bogert, 1944).

This relationship has not been experimentally analyzed in terms of behavioral factors: do learning, thermal cues, and/or visual cues affect the orientation and distribution of lizards in a thermal mosaic as a function of body size? A preliminary evaluation of these factors has been provided by observation of the behavior of lizards placed in an outdoor, artificial mosaic of shade.

This work was part of a doctorate dissertation at the University of California at Los Angeles (University Microfilms No. 68-16, 509), supported in part by a traineeship in environmental science from the National Aeronautics and Space Administration and by a grant to the Department of Zoology at UCLA (NSF GB 3871).

MATERIALS AND METHODS

Whiptail lizards of the tigris species group (C. tigris and C. maximus) were collected in the field and purchased in healthy condition from animal suppliers. They were housed in large indoor cages with 150-watt heat lamps. Lights were on for 12 hours each day, beginning at 8:00 AM. Retreats, mealworms, and water were provided.

An outdoor enclosure measuring 3 X 3 X 0.6 meters high was built at the Philip Boyd Desert Research Station near Palm Springs, Riverside County, California. The walls of the enclosure were made of colorless, transparent acetate, 0.025 inches thick, supported by stakes (3/4" pipe) and taped to rope tied between the tops of the stakes.

Inside the enclosure were placed 24 pieces of gray cardboard supported 5 cm from the ground with wire legs. Eight pieces measured 20 cm in diameter; 16 pieces, 10 cm in diameter. Thus the total of the circumferences (or diameters) of all small pieces equalled that of all large pieces; the probability that a moving lizard would intersect a small shade would be equal to that of intersecting a large shade. These cardboard canopies, two small ones between two large ones, were spaced equidistantly from one another at 8-10 cm from the wall.

Ten small lizards (5-8 cm snout-vent) were observed during activity in the enclosure. These small lizards could fit under the small cardboards without coiling. Two were juveniles of C. maximus; 8 were juveniles of C. tigris.

Eight large lizards of C. maximus (11-13 cm snout-vent) were observed similarly. These could not fit under the small cardboards unless they coiled. All could fit under the large cardboards without coiling.

On each of 10 days of observations 2-4 lizards of one size-class were introduced into the enclosure when the soil surface temperatures approached 30 C in the morning. After basking behavior became relatively uncommon, I counted the times that the lizards stopped under each size-class of shade. "Stopping" was defined as a cessation of walking lasting 15 seconds or more that did not include browsing (a lizard might enter shade for feeding rather than for thermoregulatory cooling).

Surface temperatures in the shades were taken during the observations, and correlated with the behavioral changes of the lizards.

RESULTS

LARGE WHIPTAILS. - After the initial basking period the large C. maximus began wandering along the walls of the enclosure for varying amounts of time. Lizards encountered both large and small shades in this initial exploratory period; none stopped in them.

Adults did not orient to the shade for thermoregulatory cooling until they were trained to associate the cardboard structures with the surfaces where they could cool. Lizards showed signs of thermal stress without entering shade. Thermal stress (exceeding the voluntary thermal maximum) was indicated by gaping, relatively agitated locomotion, and kinetic discoordination. Associated cloacal temperatures were 43-44 C.

Once in thermal stress, a lizard was placed in the shade so that it might learn that the cardboard canopies provided cool substrata. Each lizard was introduced to both small and large pieces of shade to reduce any training toward one size of shade. Lizards usually did not stop voluntarily in small shade, even when it was the first shade the lizard encountered.

During the first re-entry into the sun, three individuals became overheated a second time, and accordingly were introduced by hand again into the shade. No lizard overheated following 1-2 trials; each then regularly used the artificial canopies provided.

Large lizards would remain in shade for as long as 10 minutes or more, if left undisturbed. To increase the number of times a lizard stopped in shade, I would remove it from the shade after 1-3 minutes of cooling and place it in the center of the enclosure, from where it would ordinarily retreat to shade again.

The 8 large whiptails voluntarily stopped in shade 107 times. Small shade was used 4 times; large shade, 103 times ($P < .001$; Chi-square). See Table 1.

Lizards began to abandon or reject the available shade when the

TABLE 1. Use of shades of different sizes by lizards of 11-13 cm snout-vent length and of 5-8 cm snout-vent length.

	Large Lizards		Small Lizards	
Diameter of shade	20 cm	10 cm	20 cm	10 cm
Number of times selected	103	4	80	71
P (null of 1:1)	.001		.50 P .75	

surface temperatures of the shaded surfaces exceeded 41-42 C. Lizards were then in agitated states of activity; cloacal temperatures were 43-44 C. Under this environmental heat load, lizards would have to retreat underground to avoid heating above their voluntary thermal maximum.

SMALL WHIPTAILS. - The juvenile lizards regarded the pieces of cardboard as potential cooling sites throughout the experiments. None ever entered thermal stress, using behavioral criteria, and none required "training" in order to find the shade.

Juveniles did not remain in the shade longer than 2-3 minutes; they were not removed periodically from the shade in order to increase the number of choices they made.

The total of 10 small lizards stopped in shade 151 times: in large shade, 80 times; in small shade, 71 times ($.50 < P < .75$; Chi-square). There is thus no evidence that small lizards were biased in their utilization of shade. See Table 1.

Small lizards also abandoned shade once the surface temperatures in the shade exceeded about 41 C. Small pieces of shade were the first to exceed these temperatures over their entire profile, and were the first to be rejected.

DISCUSSION

Under the experimental conditions, larger lizards and smaller lizards partially segregated themselves according to the sizes of the pieces of shade. Larger lizards restricted their thermoregulatory cooling to larger cooling sites than did smaller lizards.

These data are consistent with field observations (Asplund, 1968; Duellman, 1965; Duellman and Zweifel, 1962; Zweifel, 1960) that smaller species of whiptails are often distributed in more open habitats or microhabitats than are larger whiptails, and that smaller individuals of a species occur more frequently than do adults in portions of the habitat having reduced canopies. Sympatric species pairs of Cnemidophorus ordinarily differ in body size. Such pairs might differ in physical niche as a consequence of size-related preferences for different thermal mosaics. Species of different body sizes might also differ in eccritic body temperatures, although the species and sizes used in this work appear to have the same thermal preferences, with a mean cloacal temperature of 40 C during locomotor activity (Asplund, 1968).

Results suggest that there are size-related (experience related ?) differences among whiptails regarding the visual cues that they readily associate with cooling sites. Smaller lizards did not require training to locate the shaded surfaces in the enclosure, whereas larger lizards did. The sight of a shaded surface, at least of the sizes used, can be an inadequate cue for larger whiptails. Work in progress should yield some insight as to what visual cues may be most meaningful to thermally motivated lizards.

In any given habitat, smaller lizards do have a greater number or variety of potential thermoregulatory sites than do larger lizards of the same species. It seems, accordingly, that smaller lizards might well respond to a greater variety of visual cues than might larger lizards.

MEETINGS AND SOCIETIES

CALENDAR 1971

1-4 November....SOCIETY OF VERTEBRATE PALEONTOLOGY, Annual Meeting, Washington, D.C. (with GSA).

28-29 December....HERPETOLOGISTS' LEAGUE, Annual Meeting, Philadelphia (with AAAS; cosponsored by the SSAR).

CALENDAR 1972

June.....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Boston.

July.....SALAMANDER SYMPOSIUM, Highlands Biological Station, North Carolina.

August...Combined Meeting: HERPETOLOGISTS' LEAGUE AND SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES, University of Oklahoma Biological Station, Lake Texoma.

CALENDAR 1973

4-11 August FIRST INTERNATIONAL CONGRESS OF SYSTEMATIC AND EVOLUTIONARY BIOLOGY, Boulder, Colorado.

INDIVIDUALS AND INSTITUTIONS

The ASSOCIATION OF ACADEMIES OF SCIENCE (AAS) will hold two meetings on Environmental Education (pollution, conservation, recreation) at the AAAS Meeting in Philadelphia on 27 December. The first of these meetings will be 9:00-10:30 AM, the second, 2:00-4:30 PM.

KRAIG ADLER, DAVID M. DENNIS, and DAVID H. SNYDER have been working in the Sierra Madre del Sur of Mexico. They have prepared an itinerary (showing elevations) of a trip from "Casa Verde" (about 20.5 mi N of Chilpancingo) across the mountains of Atoyac, and also a base-map of this region. These are available to interested persons upon request (Kraig Adler, Dept. Biol., Univ. Notre Dame, Notre Dame, IN 46556).

GEORGE CALLISON (Los Angeles Co. Mus. Natur. Hist.) is "putting final touches on his manuscript concerning evolutionary relationships of the New World Boidae...[and] describing an Oligocene pelobatid." (Soc. Vert. Paleont. Newslett.).

The FIRST INTERNATIONAL CONGRESS OF SYSTEMATIC AND EVOLUTIONARY BIOLOGY, sponsored by the Society of Systematic Zoology and the International Association for Plant Taxonomy, will be held at Boulder, Colorado, 4-11 August 1973.

Our change-of-address files show that herpetologists are a travelling bunch these days:

W. N. BRADSHAW (to W. Va. U., Morgantown, WV 26506); WILLIAM F. PRESCH (to U. Cal., Berkeley, CA 94720); OSVALDO K. REIG (to U. Coll. London, Gover St., London WC 1, England); MAX ALLEN NICKERSON (to Milwaukee Publ. Mus., Milwaukee, WI 53233); J. KIRWIN WERNER (to N. Mich. U., Marquette, MI 49855); RICHARD WASSERSUG (to Field Mus. Natur. Hist., Chicago, IL 60605); GERHARD A. SCHAD (to Johns Hopkins U., Baltimore, MD 21205); GEORGE R. ZUG (to New Guinea for 6 months); GEORGE GORMAN (to Coll. Virgin Islands, St. Thomas, VI 00801, for at least a year).

Also CLIFFORD R. JOHNSON (to U. New England, Armidale, N.S.W., Australia) writes that he is involved in defensive displays in Australian snakes, monitor behavior, thermoregulation in various reptiles, and the effectos of pollution and various chemical sprays on reptiles.

JAMES LAZELL (Mass. Audubon Soc.) and JOHN MUSICK (Va. Inst. Marine Sci.), collaborators with the National Park Service, write that they are working on the herpetology of the Outer Banks of North Carolina. The area is largely included within the Cape Hatteras and Cape Lookout National Seashores, where collecting is prohibited. Lazell & Musick report that initial evidence indicates that a long-snouted, heavily-whitened race of the kingsnake, Lampropeltis getulus sticticeps Barbour & Engels, is apparently valid. The black-bellied saltmarsh Natrix sipedon of this region is also apparently a valid, distinct form, but its taxonomy is complex. On the Natrix question Lazell and Musick are working in close cooperation with Roger Conant, who has amassed specimens and data from this region over many years. An apparently distinct ecological zone, with a "salt-spray climax" (Burk, C. J. 1962. The North Carolina Outer Banks: a floristic interpretation. J ELISHA MITCHELL SCI SOC 78(1): 21-28) of live oak and red cedar, and including Index plants like stemless palmetto, occurs between Cape Hatteras and Cape Lookout. Floristic and herpetological intergradation with the mainland occurs on the Banks north of Cape Hatteras.

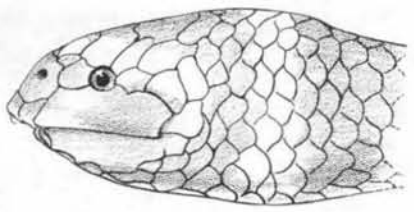
MEMBERS' DESIDERATA

ROBERT G. SPRACKLAND JR. (R.D. 1, Box 87, Jackson, NJ 08527) would like live lizards from Australia, Asia, and Africa for a project concerning comparative behavior and interrelations of genera.

GARY EBERLE (Mus. Zool., Louisiana State Univ., Baton Rouge, LA 70803) needs live specimens of Clonophis kirtlandii and Thamnophis butleri for chromosome studies.

THOMAS ZACCONE (Dept. Herpetology, American Museum of Natural History, New York, NY 10024) would appreciate live specimens (with locality data) of Diadophis and Heterodon for chromosome studies.

TERRY E. GRAHAM (Dept. Biol., Worcester State Coll., Worcester, MA 01602) is attempting to assemble a teaching collection of preserved herps of the eastern U.S. He would like to hear from collectors who might be able to provide him material with locality data. He will provide a want list upon request, and will be happy to arrange for transportation of the specimens. He is also interested in purchasing, for cost of duplication, color slides of North American herps.



H. BERNARD BECHTEL (2101 North Patterson, Valdosta, GA 31601) is compiling a file of the laws that pertain to amphibians and reptiles, pro and con. He would appreciate copies or references to new laws that are passed, and to have old and obscure laws brought to his attention. The results of this compilation are expected to be published in the 1972 YEARBOOK OF HERPETOLOGY, and if possible portions will be published in H R.

STEVEN WEINKSELBAUM (3010 Clarendon Road, Brooklyn, NY 11226) is interested in buying or trading for out-of-print or rare books on herpetology.

PAUL L. SWANSON (R.D. 2, Polk, PA 16342) would like to sell his copies of COPEIA (1931-1951, 1952 (1,2), and #170 (1929), a total of 83 copies), and HERPETOLOGICA (vol. 1-7, 13).

PETER J. KAPLAN (7 Harwich Rd., Providence, RI 02906) would like to contact anyone who has had experience keeping pygopodid lizards in captivity.

JAY M. SAVAGE (Dept. Biol. Sci., Univ. Southern Calif., Los Angeles, CA 90007) is working to complete his checklist and key to the amphibians of Costa Rica, so that it may appear in published form prior to the meetings of the ASIH in Costa Rica during 1973. For this reason, he would like to be kept informed of plans for publication, of descriptions of new Costa Rican species, of records of species previously unknown in the Republic, or of specimens establishing substantial range extensions in Costa Rica, so that the manuscript may be kept up to

date with the latest information until going to press. Workers with publication plans are urged to proceed as rapidly as possible so that their material may be included in the checklist.

CRAIG E. NELSON (Dept. Zool., Indiana Univ., Bloomington, IN 47401) would like live Ambystoma, collected from in or near breeding congresses, for interspecific hybridization experiments. Nominal sum paid (call 812-337-9485 for additional details).

L O S T M E M B E R S

Publications of the SSAR or H L have been returned from the following addresses marked "Not Known" or "No Forwarding Address." We would appreciate any aid in obtaining current addresses for these members.

STEVE D. AIRD, 127A Langford Hall, Montana State Univ., Bozeman, MT 59715.

LEE ROBERT BAKER, Dept. Biol. Sci., Nevada Southern Univ., Las Vegas, NV 89109.

JERRY SULLIVAN, 7814 Junior #1, Houston, TX 77017.

BENTON B. ANDERSEN, Biology Museum, Univ. Nevada, Las Vegas, NV 89109.

RICHARD DUNN, P.O. Box 613, Arcadia, CA 91006.

CLIVE J. LONGDEN, 1525 McCaskill St. (Apt. 1), Tallahassee, FL 32304.

JEREMY PENNER, 757 De Barr, Norman, OK 73069.

MIKE CHRISTENSON, Weatherford Apts. 30, Weatherford, OK 73096.

IF YOUR ADDRESS HAS CHANGED

Please send old and new addresses directly to the address below. We will make changes for SSAR, H L, and the CATALOGUE.

Herpetological Catalogue Comm.
Amer. Mus. Nat. Hist.
New York, N.Y. 10024

CHANGES OF ADDRESS

Please inform us of your address changes as soon as possible. Each returned copy of HERPETOLOGICAL REVIEW costs us (and you) about 25 cents more in postage and considerably more in handling.

Send address changes directly to:

HERPETOLOGICAL REVIEW
Genera of Reptiles Project
American Museum of Natural History
New York, N.Y. 10024

We will see that changes go to the mailing lists of SSAR, Herpetologists' League, and CATALOGUE, as well.

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be type-written on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $23.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/8 inches (one column) or 9 1/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 12 3/4 inches). Line cuts are reduced about 25 per cent in processing. [See also the special instructions for "Un-reviewed."]

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

UNREVIEWED-UNEDITED COMMUNICATIONS

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions. Drawings should be made to widths of 3 1/2" (one column), 7 1/4" (two columns), or 11" (three columns). Each vertical inch of drawing takes up six lines of text. The three-column format allows about 270 four- to five-word lines (35 characters and spaces) per page.

Page charges are: $20 for a single page; $40 for the two-page maximum. Include an allowance for the title and author's name and five lines for the address and received date. Send a check for the proper amount with the manuscript. Or, if you prefer, we will bill you that amount for reprints.

S S A R

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

The SSAR encourages the acquisition of knowledge on amphibians and reptiles, and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communications between amateur and professional workers.

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society; they receive the JOURNAL OF HERPETOLOGY, HERPETOLOGICAL REVIEW, and issues of the Facsimile Reprint Series. They also receive reductions on the price of other Society publications. See the last page of this issue for information on membership and subscriptions.

E D I T O R I A L

The AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, at its annual meeting in June, allowed a second step to be taken toward the unification of herpetologists and their information systems. [The first step was the "Unification Committee," appointed by the SSAR and the H L in December, 1970.] The ASIH Board of Governors approved the transfer of the CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES from ASIH sponsorship to that of the SSAR.

The members of the Catalogue Committee had voted unanimously to request this move in December, 1970, and it was notable that the ASIH Board allowed the release of the Committee and its assets without opposition from any member.

The Committee members believe that association with a purely herpetological society will strengthen its base of support within the community. In turn, the assets of the Catalogue will serve to strengthen the financial base of the SSAR. -- HGD.

HERPETOLOGISTS' LEAGUE

The Herpetologists' League is an international organization established by Major Chapman Grant in 1936. It is dedicated to furthering knowledge of the biology of amphibians and reptiles.

In 1970 it had 940 members and fellows, 24 life members, 10 honorary members, and 400 institutional subscriptions to its journal, HERPETOLOGICA.

All persons interested in herpetology are eligible for membership. Members receive HERPETOLOGICA (and now HERPETOLOGICAL REVIEW), to which they can submit manuscripts for publication. They may also present papers at the Annual Meeting.

See the last page of this issue for information on membership and subscriptions.

PROGRAM

OF THE

ALBUQUERQUE

MEETING

18 - 22 August 1971

WEDNESDAY, AUGUST 18, 1971

9:00 AM Board Meeting
Biology 167

12:00 NOON Lunch

1:30 PM Resume Board Meeting
Biology 167

3:00 PM Early registration and check in
Biology 37 and
Santa Clara Dormitory

THURSDAY, AUGUST 19, 1971

8:00 AM Registration (all day)
Biology Building

8:00 AM Dormitory Check-in
Santa Clara Hall

9:00 AM Herpetology Division Open House
Biology 35, 37, 52

9:30 AM Field Trips
To be announced

2:00 PM Wives get-together
To be announced

2:00 PM Herpetology Division Open House and Round-table Discussion of individual herpetological interests.
Biology 35, 37, 52

8:00 PM Smoker and Social
To be announced

FRIDAY, AUGUST 20, 1971

8:30 AM CALL TO ORDER: Robert E. Gordon (University of Notre Dame), Chairman of S.S.A.R.

WELCOME: Ferrel Heady, President, The University of New Mexico
New Mexico Union

Invited Papers on the Theme: THE ECOLOGY OF ARID-ADAPTED AMPHIBIANS AND REPTILES, Charles M. Bogert, Presiding.

8:45 AM EVOLUTION AND BIOGEOGRAPHY OF THE SOUTHWESTERN HERPETOFAUNA. Charles H. Lowe (Univ. of Arizona).

9:30 AM TRANSIENT ENERGY BUDGET STUDIES: THEIR IMPLICATIONS FOR ANALYSIS OF BEHAVIOR, PHYSIOLOGY, AND PREDATOR-PREY INTERACTIONS OF DESERT REPTILES AND OTHER ANIMALS. Warren P. Porter, J.W. Mitchell, W.A. Beckman and C.B. De Witt (Univ. of Wisconsin, Madison).

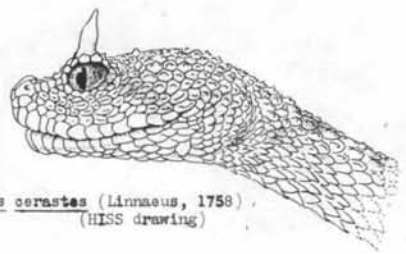
10:15 AM Coffee Break
Snack Bar

10:30 AM Business Meeting: "WHERE DOES SSAR STAND TODAY?"
New Mexico Union

11:45 AM Group Photo
To be announced

1:00 PM INVITED PAPERS (continued)
New Mexico Union

1:00 PM WATER AND ELECTROLYTE BALANCE OF DESERT REPTILES. John E. Minnich (Univ. of Wisconsin, Milwaukee).



1:45 PM ENERGY FLOW IN SOUTHERN NEVADA POPULATIONS OF UTA STANSBURIANA: A THREE-YEAR ANALYSIS. Frederick B. Turner, Bruce W. Kowalewsky and Philip A. Medica (Univ. of California, Los Angeles).

3:00 PM Coffee Break

3:30 PM TEMPERATURE REGULATION IN DESERT AMPHIBIANS AND REPTILES: PAST, PRESENT, AND FUTURE STUDIES. Bayard H. Brattstrom (Calif. State Coll., Fullerton).

4:15 PM FOOD NICHE DIMENSIONALITY AND OVERLAP IN THREE SYMPATRIC SPECIES OF SCAPHIOPUS. Arthur E. Dunham (Univ. of New Mexico).

8:00 PM Banquet

Cerastes cerastes (Linnaeus, 1758).
(HISS drawing)

SATURDAY, AUGUST 21, 1971

CONTRIBUTED PAPERS

9:00 AM A HISTOLOGICAL STUDY OF THE THIRD EYE AND RELATED STRUCTURES IN SCINCID LIZARDS. G. Craig Gundy and Charles L. Ralph (Univ. of Pittsburgh).

9:20 AM EFFECT OF NUTRITIONAL STATUS ON TEMPERATURE REGULATION IN THE LIZARD KLAUBERINA RIVERSIANA. Arthur B. Robertson (New Mexico State Univ.).

9:40 AM WATER LOSS IN AGGREGATED VS. ISOLATED SALAMANDERS. Westley Lagerberg and Bayard H. Brattstrom (Calif. State Coll., Fullerton).

10:00 AM Coffee Break

10:30 AM FIELD OBSERVATIONS OF AGGRESSION BETWEEN GRAVID ANEIDES AENEUS FEMALES IN A NEST CREVICE. David H. Snyder (U. of Notre Dame).

10:50 AM VARIATION IN THE LIFE HISTORY OF THE SALAMANDER GYRINOPHILUS PORPHYRITICUS. Richard C. Bruce (West. Carolina Univ.).

11:10 AM POLARIZED LIGHT: POSSIBLE SIGNIFICANCE OF THE PLANE OF POLARIZED LIGHT IN ORIENTATION OF SALAMANDERS. Douglas H. Taylor (U. Notre Dame).

11:30 AM CONTROL OF THE CIRCADIAN RHYTHM OF LOCOMOTION IN TARICHA GRANULOSA. Jeffrey L. Briggs (Wisconsin State Univ.-Whitewater).

SUNDAY, AUGUST 22, 1971

8:00 AM CHECK-OUT OF DORMITORY (by 10:00 AM)

8:00 AM FIELD TRIPS

Photograph of Eumeces inexpectatus with her nest in situ, in a "hammock" near Miami, Florida. David Molchos (9400 Martinique Dr., Miami, FL 33157).

BRATTSTROM, BAYARD H. (Calif. State Coll., Fullerton). Temperature regulation in desert amphibians and reptiles.

The initial studies on thermoregulation in desert reptiles by Cowles and Bogert showed that these ectotherms regulated their body temperature by behavioral means. Recent studies have shown that temperature regulation in desert amphibians and reptiles is not only behavioral, but involved a large number of subtile and effective physiological mechanisms that are used by these forms to modify their physiology independent of temperature or to regulate their body temperature by physiological mechanisms. This diversity of mechanisms allows desert amphibians and reptiles to exploit the thermal mosaic of the desert environment for the best utilization of energy sources with the least amount of competition.

Briggs, Jeffrey L. (Wisconsin State University-Whitewater). Control of the Circadian Rhythm of Locomotion in Taricha granulosa.

Over 56,000 hours of locomotor activity of Taricha granulosa were recorded using two types of low cylindrical plastic monitoring chambers. This species shows distinct rhythms of activity under normal day-night cycles, shortened day-night cycles, constant darkness (DD) and constant light (LL). The rough-skinned newt is day active and crepuscular. I found that 62% of the animals tested show their peak activity within 8 hours of the light-on cue and 71% within 12 hours. The activity peaks are random with respect to the light-off cue. In addition they follow "Aschoff's Rule" for circadian rhythms as it applies to day-active animals: (1) They show a longer period under DD (mean=24.72 hours) than LL (mean=23.7 hours) and (2) the period decreased with increasing intensity of light under LL. However, the number of animals which show arrhythmia increased with increasing intensity. Entrainment to the light-dark cycle is evident and the activity cycle could be phase-shifted by changing the phase relationship of the light cue. Although newts can entrain to temperature pulses (cold from 9°C to 4°C) under constant light, they entrain to the light cycle when given a choice between light and temperature. Activity generally ceases below 6°C regardless of the state of the light-dark cycle. There is no apparent difference between eyeless and intact newts in the ability to use light cues in entrainment. The site of the receptor was narrowed only to the dorsal midbrain

---

BRUCE, RICHARD C. (West. Carolina Univ.). Variation in the life history of the salamander Gyrinophilus porphyriticus.

Two life history patterns, designated alpha and beta, were observed in populations of Gyrinophilus porphyriticus in the Blue Ridge Mountains of North and South Carolina. Alpha populations from the Blue Ridge Embayment and adjacent regions are characterized by early attainment of sexual maturity following metamorphosis, small adult body size, and small clutch size. Beta populations from the Nantahala and Balsam Mountains show delayed attainment of sexual maturity following metamorphosis, large adult body size, and large clutch size. Clutch size increases with body size in each population, but the relationship differs in alpha and beta groups. The distribution of body sizes is similar for males and females in each population; however, males mature at a smaller size than females. All populations show a 1:1 sex ratio. The findings suggest that the current taxonomic arrangement for this species in the southern Blue Ridge is misleading and inadequate.

Dunham, Arthur E. (The University of New Mexico) Food niche dimensionality and overlap in three sympatric species of Scaphiopus.

In spite of its central importance in current population theory, few studies of food niche dimensionality and overlap among closely related sympatric species have been forthcoming. This paper documents interspecific and intraspecific differences in certain parameters of the food niche among three sympatric species of Scaphipus occurring in New Mexico. The breadth of the food niches of these three species of toads were determined with regard to prey size and the amount of energy obtained from each prey species. The degree of overlap among the food niches of these three closely related species was measured. The process of resource allocation along the gradient of prey size is demonstrated. The distribution of the prey items in the diets of each of these three predators is compared to the relative abundance of the prey species in the field. These toads approach the range of available prey items as a mixture of at least three coarse grained patches. Additionally, an information theory index of food niche breadth is used to compare toad populations in which the number of anuran species varies. Evidence is presented lending credence to the contention that interspecific competition is responsible for positioning of niche boundries.

GUNDY, G. CRAIG and CHARLES L. RALPH (Univ. of Pittsburgh). A Histological Study of the Third Eye and Related Structures in Scincid Lizards.

The morphology of the parietal eye and related dorsal circumventricular structures was studied in seven species of the family Scincidae, including one species from the subfamily Acontinae and one from the subfamily Feylininae. Formalin-fixed specimens were embedded in paraffin, sectioned at 10 microns, and were stained in hematoxylin and eosin and Patay's triple stain. The limbless burrowing species Acontias percivali and Feylinia currori both lack a parietal foramen. There is a thinning of the bone in Acontias, but no trace of a foramen in Feylinia. Both species, especially Acontias, have degenerate parietal eyes. Riopa sundevalli and Chalcides chalcides are forms with reduced limbs. Chalcides, the more primitive of the two (according to Greer,1970), has a well-developed parietal eye and foramen. Riopa has an elaborate parietal eye, but there is only a thinning of the skull rather than a definite opening. Eumeces obsoletus, Eumeces fasciatus, and Lygosoma laterale are diurnal species with well-developed limbs. They all have a large parietal foramen and a well-developed parietal eye. These data suggest that a subterranean habit may result in regression of the parietal complex. This is consistent with the current hypothesis of a photoreceptive function for the parietal eye.

LAGERBERG, WESTLEY and BAYARD H. BRATTSTROM (Calif. State College, Fullerton). Water loss in aggregated vs. isolated salamanders.

The salamanders, Aneides lugubris, A. ferreus, and A. flavipunctatus tend to isolate themselves when placed in simple aquaria with numerous rock caves. If the aquarium sand is allowed to become dry, the Aneides will aggregate. Such aggregation would reduce water loss by reducing the surface area exposed to the air and sand. Tested experimentally in an open air-flow system, three isolated Aneides flavipunctatus (combining weights) lost weight considerably faster than three aggregated A. flavipunctatus. Aggregation behavior is thus a useful mechanism to avoid desiccation.

LOWE, CHARLES H. (Univ. of Arizona). Evolution and Biogeography of the Southwestern Herpetofauna.

(Abstract not received).

MINNICH, JOHN E. (Univ. of Wisconsin). Water and Electrolyte Balance of Desert Reptiles.

Although reptiles have been successful in occupying deserts, few studies have been performed on their water and electrolyte budgets in the field. Because they occupy a dry, seasonally hot environment, desert animals face problems of procuring and conserving sufficient water. Unlike certain desert rodents, reptiles cannot balance their water losses through the production of metabolic water. They usually obtain most of their water from their food. The osmotic and electrolyte concentrations in the food of most desert reptiles frequently exceeds those of their body fluids. This, coupled with the loss of ion-free water through evaporation, makes it necessary for them to excrete electrolytes with a small loss of water.

During the driest time of the year, certain reptiles exhibit decreases in body water content and changes in body fluid distribution (Amphibolurus ornatus, Sauromalus obesus), but others do not (Dipsosaurus dorsalis, Uma scoparia). Osmotic and electrolyte concentrations increase in the body fluids of A. ornatus and Gopherus agassizii, but do not change in most other species (D. dorsalis, S. obesus, U. scoparia).

Several species drink rainwater when it becomes available, but most do not rely on drinking for maintenance of normal body water and electrolyte content. Two important exceptions are A. ornatus and G. agassizii. Rainwater consumed by A. ornatus is used to excrete sodium stored during dry periods. G. agassizii drinks rainwater and stores it in the urinary bladder, where it functions as a water reserve.

Reptiles curtail evaporative water losses by behavioral means. During summer they are active during the cooler daytime hours or at night. When inactive, they spend long periods in burrows, where the higher humidities and minimal activity curtail water losses. Certain species (G. agassizii, S. obesus) become inactive for several days during the driest part of the year.

Desert reptiles excrete most salts with a minimal water loss through a nasal salt gland and in the urine as insoluble urate salts. Much of the ingested potassium and most chloride, along with lesser amounts of sodium and bicarbonate, are excreted through the salt gland. In certain species (e.g., A. ornatus) the salt gland is absent and in most others the salt gland is incapable of excreting all of the ingested salts. Most of the remaining potassium and sodium are excreted in the urine as urate salts. The low solubility of these salts, coupled with water reabsorption form the cloaca, permit excretion of large quantities of inorganic cations with a small loss of water. The desert tortoise stores urate salts and uric acid in the bladder for long periods.

PORTER, W.P., J.W. MITCHELL, W.A. BECKMAN and C.B. DE WITT (Univ. of Wisconsin). Transient Energy Budget Studies: Their Implications for Analysis of Behavior, Physiology, and Predator-Prey Interactions of Desert Reptiles and Other Animals.

Transient energy balance models have been developed for bare-skinned animals and for desert micrometeorology. The models predict animal temperatures and locations in the environment as a function of time of day and day of the year. As an explicit example, the activity patterns for the desert iguana, Dipsosaurus dorsalis are outlined. The development and testing of the models in the laboratory and in the field are described. Predicted activity patterns of other animals are also described. Intergration of the patterns and some field tests of the predictions are discussed as well as additional potential uses for the tools we have developed.

ROBERTSON, ARTHUR B. (New Mexico State Univ.). Effect of nutritional status on temperature regulation in the lizard Klauberina riversiana.

In order to further elucidate physiological parameters of the phenomenon of preferred body temperature, a study was conducted to determine the effect of diet on the pb+. Six animals were fed and watered and six animals were watered only for two weeks at a time. Six runs were conducted; cloacal temperatures were taken each day; the first three runs were under a constant light regime, the last three runs were under a L:D::6:18 pattern. Each animal was provided with a thermal gradient ranging in temperature from 10°C at the cold end to 85°C under the heat lamp. During the first 3 runs there was no significant difference in body temperatures of the starved and fed groups. There was an initial drop in temperatures of both groups from day one to three; then temperatures stabilized throughout the remainder of the run. Upon initiation of the light cycle L:D::6:18, the temperatures of the two groups diverged significantly with fed animals maintaining a higher body temperature. The initial drop in temperatures for the first few days was not as apparent. This work illustrates the lability of the preferred body temperature and suggests reduction of body temperature in response to starvation may be an adaptive mechanism to withstand periods of reduced food availability.

SNYDER, DAVID H. (U. of Notre Dame). Field observations of aggression between gravid Aneides aeneus females in a nest crevice.

In late May, 1970, night observations were made of a rock crevice population of Aneides aeneus at Highlands Biological Station in western North Carolina. A prolonged and intense aggressive encounter, involving forebody-bobbing, lunging, tail lashing and biting was observed between two gravid females occupying the same nest crevice. This crevice was subsequently used as a nest site by a single female. A male in the same crevice was not directly involved in the aggression, though he did briefly court one of the females. The literature on aggression in salamanders, which is reviewed, is meager and has usually concerned captive animals.

TAYLOR, DOUGLAS H. (U. Notre Dame).

Polarized light: possible significance of the plane of polarized light in orientation of salamanders.

Tiger salamanders (Ambystoma tigrinum mavortium) were trained along a specific axis in an indoor training tank under polarized light. Indoor orientation tests were conducted in a circular arena completely enclosed in black plastic. Under the same polarized light source in the test arena, the directional responses of the salamanders was the same to the plane of polarization under which they had been trained. Shifting the plane of polarization by 90 degrees, in either direction, resulted in corresponding shifts in the orientational responses of the salamanders. (Supported by NSF Postdoctoral Fellowship No. GU-2058, Indiana Academy of Science Grant 95074 and by NIH Biomedical Grant NIH-FR07033-05 to K. Adler)

TURNER, FREDERICK B., BRUCE W. KOWALEWSKY and PHILIP A. MEDICA (Univ. of California). Energy flow in southern Nevada populations of Uta stansburiana: A three-year analysis.

Energy flow of Uta stansburiana in southern Nevada was estimated for a three-year period (1965-8) using a computer model calculating hourly changes in body temperatures of individuals and daily changes in the numbers and body weights of individuals making up the population. Annual energy flow ranged from 0.18 Kcal/m2 in 1965-6 to 0.27 Kcal/m2 in 1966-7. Annual production ranged from 0.033 Kcal/m2 in 1965-6 to 0.056 Kcal/m2 in 1967-8.

Ratios of production to energy flow varied from 18% (1965-6 and 1966-7) to 27% in 1967-8 (cf. 1-2% in birds and mammals), so Uta is similar to ectothermic invertebrates in this respect. Uta annual energy flow (ca. 0.2 Kcal/m2) was only about 3.5% that of Dipodomys merriami and 9% that of Lepus californicus in southern Arizona, but exceeded the energy flow of three of the eight resident mammals studied by the Chews. Annual production by Uta (ca. 0.046 Kcal/m2) was about the same as that reported for Dipodomys merriami in Arizona (0.053 Kcal/m2) and exceeded that of the other southern Arizona mammals.

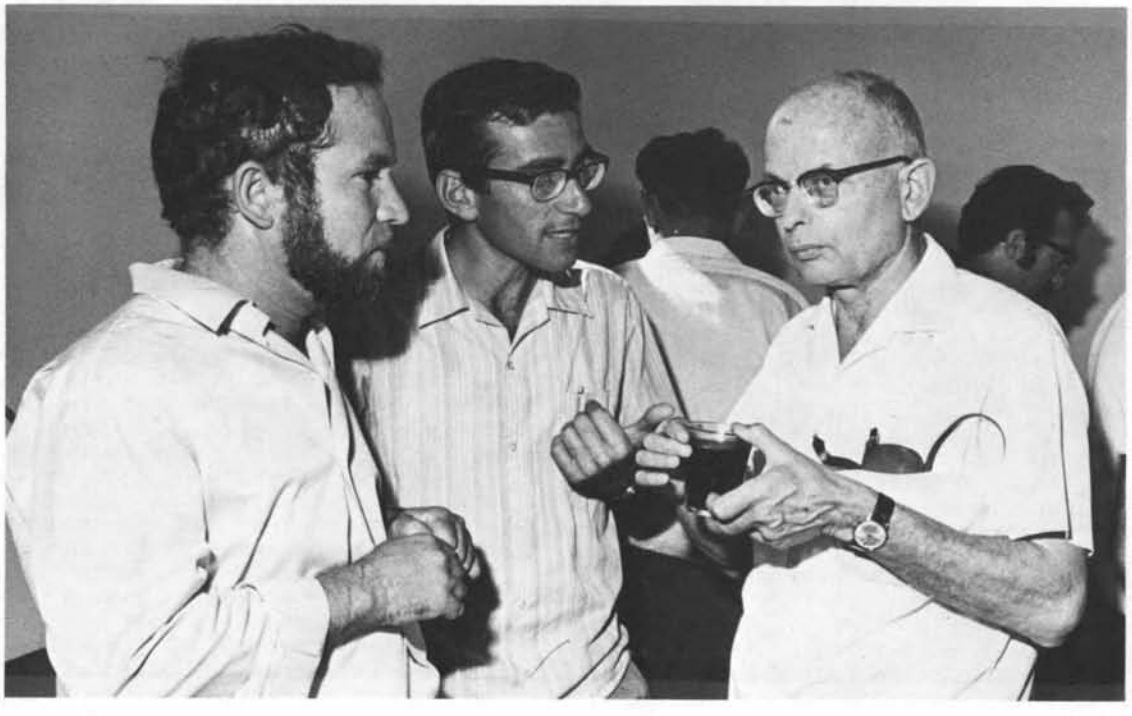
The energy flow analysis was predicted on the lowest existing measurements of Uta respiratory metabolism (Roberts); estimates of total metabolism using measurements by Dawson and Bartholomew were 3-4 times higher. The use of these latter respiratory rates would increase energy flow estimates roughly 3-fold and lower the production/energy flow ratios to around 6.5 - 8%. There is no clear-cut rationale for choosing between the two physiological models.

HERPETOLOGY AT

אוניברסיטת תל-אביב

TEL-AVIV UNIVERSITY

H. Mendelssohn celebrated his 60th birthday on 30 October 1970. Instead of the usual "Festschrift," his associates presented him with a cover (see photo) in which dedicated articles published in various journals will be assembled. He was recently awarded the "Weizmann Prize in Natural Sciences" by the Tel-Aviv Municipality.



One of Mendelssohn's students is continuing work on the behavior of Agama stellio and A. agama lionotus. Avner Bdolah and students, working in Elazar Kochva's laboratory, are separating, purifying, and preparing antisera of enzymes from Vipera palaestinae venom, to be used in following the synthesis and secretion of these components by the venom glands. Raya Brown is doing the final calculations of enzyme secretion for her Ph.D., and Gedalia Frenkel's "Visceral anatomy of Vipera palaestinae: an illustrated presentation," has just appeared in the Israel Journal of Zoology.

Israel Duvdevani has finished his Ph.D. dissertation on salt and water metabolism of Acanthodactylus lizards, in which he describes the differences between the four Israeli species inhabiting arid and semi-arid biotopes. He found salt glands in all, and recorded the lowest oxygen consumption and evaporative water loss in A. boskianus, which is considered the best desert-adapted species of the genus. -- EK.

(ABOVE) Cover of "non-festschrift" dedicated to Dr. Mendelssohn, prepared by R. Kalef. (Photo by A. Shoob.)

(BELOW) H. Mendelssohn (right) at his birthday celebration on 30 October 1970, with some of his associates. [Both they and the reptile in his pocket are unidentified.] (Photo by A. Shoob.)

SCIENTIFIC HERITAGE OF AN EMINENT SOVIET HERPETOLOGIST

(In memoriam Prof. Pavel Viktorovich Terentyev, 1903-1970)

By L.J. Khosatsky and I.S. Darevsky

On December 30, 1970 in Leningrad at the age of 67 passed away a well-known Soviet Zoologist, prominent specialist in the fields of batracho-herpetology and biometrics, professor of the Leningrad State University P.V. Terentyev.

Pavel Viktorovich Terentyev was born in Sevastopol on December 23, 1903. Educated by his family in the spirit of striving for the heights of knowledge and devoted service to Science, he showed a passion for natural sciences from eary childhood. Having entered the Moscow State University he began his scientific activity as an assistant at the Darwin Museum in Moscow when he was but an eighteen-year old student. Later, already a research scientist in herpetology, he was placed at the head of the Scientific Department of a large terrarium of the Moscow Zoological Gardens. He then worked in a number of scientific institutions of Moscow, Kazan, Arkhangelsk etc. Beginning in 1934, and up to the day of his death, his life was closely bound to the Leningrad State University where he worked his way up from Assistant to Professor of Vertebrates in the Department of Zoology. From 1954 to 1965 he was the head of this Department; it was he who later organized the Scientific Section of Biometrics, at the University, at the head of which he stood all the last years of his life.

Beside his work at the University, P.V. Terentyev for a number of years worked at the Zoological Institute of the Academy of Sciences of the USSR.

His interest in exhaustive study of amphibians and reptiles awoke in his early years and accompanied him through all his life; his fruitful activities in this branch make hime one of the best herpetologists of our time. It is probable, however, that the outstanding progress for which herpetology is obliged to the scientific work of P.V. Terentyev was achieved mainly because the scientist never confined himself to any narrow branch of investigation. Being a zoologist of a broad University-type he showed keen interest in a variety of problems and trends of general biology.

He left a bright trace in the investigations of theoretical systematics, biogeography, and - particularly - in biometrics. The use of mathematical methods in the solution of biological problems had a strongest and permanent attraction for P.V. Terentyev from his very youth. He was an ardent propagandist of deep research in the development of biometric theory and methods; his own contribution in this field has been very important, particularly in the solution of a number of complicated problems of amphibian and reptile systematics. At the same time, for a versatile development of the application of biometrical methods to a possibly wide range of objects, P.V. Terentyev investigated from this point of view not only the amphibians and reptiles, but also fishes, birds, molluscs, and even some plants. His cherished dream was to use a wide range of the most important groups of organisms as simulation objects for the building of the theory of biometrical methods.

Scientific interests of P.V. Terentyev in the field of batracho-herpetology from the very beginning of his scientific activity were mainly within the range of research of amphibians, primarily of ecaudates. Being for a long time largely recognized as a batrachologist, P.V. Terentyev gave much consideration to the study of reptiles, since he was always true to his idea of maximum broadening of the field of scientific research. His most important scientific achievements in these two sections of vertebrate zoology were reflected in many publications, and primarily in some of his monographs. First of all we must mention here "The Key to Reptiles and Amphibia", which he wrote in collaboration with another prominent Soviet herpetologist the late S.A. Chernov.

This book is by far broader than a usual "Key". Being essentially a concise encyclopaedia of Soviet Union batracho-herpetology, this book, - after the well-known summaries by A.M. Nikolsky (1905, 1915, 1918), - gives in a concise form and at a modern level of science all the basic data on amphibia and reptiles of this country and thus of a large portion of our planet. Therefore it is but natural that the book found a wide response and ran into five editions, including one English edition (the first Soviet edition appeared in 1936, the last - in 1949, the English edition in 1965).

P.V. Terentyev's "Herpetology" (1961, English edition -- 1965) is of great interest for both scientists-zoologists and for students, being one of the first works of this kind in the world zoological literature. The author undertook the difficult task of giving an integrated review of the philogenesis, particular systematics, geographic spreading, and some data on the biology of the lower terrestrial vertebrates. The author used here a most original way of reducing the characteristics of taxonomic groups (including major genera) into Swedish dichotomic tables; though it made the characteristics too concise, it saved much space. Of very great value are the maps of the distribution of all existing families of amphibians and reptiles, as well as original phylogenetic diagrams worked out at family level for the existing groups, and at ovdinal level for those extinct. Special

chapters dealing with the problems of origin of amphibians and reptiles are also of considerable interest.

"The Frog" (1950) - a large monograph by P.V. Terentyev - holds the lead among his scientific publications. Published in a series of text-books for the deeper study of laboratory animals, this monograph surpassed by far the usual publications of this type both by its general content and the level of scientific thought. The largest section of the book deals with frog morphology, which is considered in a detailed description of separate systems of organs. The author also considered the general structure of these animals and the variability of external characteristics. The section dealing with systematics considered the phylogenetic interrelations of suborders and families of ecaudates, as well as the subgenera and species of the genus Rana. Major data on frog ecology are also given there in adequate detail.

P.V. Terentyev published about 150 papers, mainly on batracho-herpetology. The versatile research activity of the scientist involved various problems of amphibian and reptile biology. He also studied very intensely the above-mentioned animals from the point of view of faunistics, systematics, and zoogeography. The problems of the use of methods of mathematical statistics play a special role in his scientific activities in the above branches of zoology. The researches of P.V. Terentyev in the field of biometrics were carried out mainly in connection with the study of amphibians and reptiles, the result being that complex problems in the systematics and zoogeography of amphibians and reptiles found new and convincing solutions. At the same time some general essential theoretical problems of biometries were developed in using the batracho-herpetological material. Investigations in the problems of theoretical systematics form another important part in the scientific heritage of P.V. Terentyev. A more detailed consideration of the above-noted trends in his scientific activities is given below.

Some of the early papers by P.V. Terentyev, comprising his first scientific publications are concerned with the study of amphibia and reptiles as representatives of faunistic complexes which characterize the nature of certain regions and localities of the Soviet country. Among this group of publications on faunistics, attention is attracted by a small book published in 1924 on amphibians of the former Moscow province. Though written by a very young scientist, the book gives an interesting and adequately complete review of Moscow region batrachofauna. Together with other data, the book gives identification tables for families and species of amphibia inhabiting the central regions of the European part of the USSR, which were compiled by the author, and also a table for identifying the larvae and spawn of these species. In other herpetofaunistic papers the author deals with data on chuvashia, the North Caucasus, and the Sakhalin and Kuril islands.

PAVEL VIKTOROVICH TERENTYEV

An extensive series of Terentyev's works on the systematics of ecaudate amphibia is the best known and attracts the keenest attention of batrachologists. The most important among the works of this series are his investigations on the taxonomic position of the brown frog and the green frog. The author also investigated the taxonomic correlation between different forms of the genera Bombina, Pelodytes, Bufo, and Hyla. P.V. Terentyev's contribution to the study of systematics of different representatives of batrachofauna was very significant: he developed the techniques of taxonomic analysis of separate forms, and the standardization of the technique of this study. In this respect he thoroughly worked out standard diagrams of amphibia morphometry, evaluated the relative value of various measurements, and suggested the most important indices. The author paid great attention to the study of peculiarities in geographic variability of different taxonomic characteristics of amphibia, and of green frogs in particular. All data of the taxonomic study of any given form were always subjected to biometrical analysis, which revealed the basic regularities of individual, age and geographical variability.

Zoogeographical studies of P.V. Terentyev are closely bound to his purely taxonomic works. His above-mentioned works on the study of geographic variability of amphibia allowed him to come to a conclusion that this variability is characterized as a rule by the so-called clinal type of successive transformations of different morphological characteristics. He made interesting suggestions on the variable size of ranges of different animal species and on the wealth of island faunae; in connection with that he developed a foundation for the rule

of correlation between the number of species and the size of area they inhabited. His most important zoogeographical work should be considered as a very interesting experience in the use of mathematical statistics in this field. This work, for which the author was awarded the degree of Doctor of Sciences in Biology, is an original analysis of quantitative data on the geographical distribution of nearly all the snakes of the world fauna, taking into account the size of species and generic ranges. A special emphasis is made here on finding the relation between the number of snakes in different faunae and their belonging to a particular geographical zone, characterized by certain climatic temperatures. P.V. Terentyev studied in particular the relation between climatic temperatures and the size of snakes and ecaudate amphibia: as a result of these studies he found it possible to state that there exists a regular relation between absolute dimensions of the body both for warm- and cold-blooded animals and the environment temperature. This relation, however, has no direct expression, but is characterized by differences in types of organism response to the action of temperature and other environmental factors in different conditions. In accordance with this statement, P.V. Terentyev demonstrated in particular that the well-known "Bergman rule" is not of absolute value and obeys the universal rule of optimum as a particular case. The most favourable existence in the zone of optimum effect of a particular factor for the given organism generally results in a maximum increase of body size; any deviation from the optimum, on the other hand, results in oppressing the organism and in the reduction of its size. The universal character of the optimum rule, as demonstrated by P.V. Terentyev, is a universal biological regularity, which implies physiological, taxonomic, and biogeographical phenomena.

On the base of the exhaustive taxonomic study of different animals and - primarily - of amphibia and reptiles, P.V. Terentyev, as already stated, made an important contribution to the theory of biometrics. We can here but briefly mention his studies of the actual value of Pirson-type distribution curves for biological objects, of the part played by the index-method in systematics, of the possible use of variance and iteration method for evaluating the qualitative riches of fauna, and for quantitative stock-taking of animals. But the greatest theoretical and practical value in this fiels is the doctrine of correlation pleiads of taxonomic characteristics which he has developed. The part played by this doctrine and by the actual techniques of taxonomic analysis which are based on it should receive the highest possible estimate; these techniques find now an increasingly wide use both with zoologists and botanists.

Many of Terentyev's works are very important for theoretical systematics and for the evolution theory. It should be noted in this respect that he was the first to apply the rule of parallel rows of homological characteristics to amphibia. The study of the already mentioned clinal geographic variation of the intra-species forms in connection with the ideas on the mechanism of microevolution brought him to the conclusion that microclines are a special form of adaptation. He paid great attention - and particularly in the last years of his life - to the development of the ideas on the taxonomic indivisibility of species, which he believed to be the final taxon.

P.V. Terentyev was a prominent and many-sided zoologist, his contribution to the science was very important, his approach to the solution of complex scientific problems was always original and creative. He was a gifted teacher and popularizer of science, the author of a number of excellent textbooks, of many popular-science papers and booklets discussion different topics. A splended lecturer and debator he often delivered lectures and addresses not only as an honoured University professor but also outside the walls of his "alma mater" to different audiences. His picturesque and interesting speech never left the hearers indifferent. Among his other important merits we should underline his work on science organization, for example the organization and carrying out in 1958-1964 of four very representative conferences in Leningrad on the problems of application of mathematics in biology. Two large herpetological conferences in Leningrad, in 1964 and 1967, which were held under his guidance, played an important part in the consolidation of Soviet batrachologists and herpetologists. Together with S.A. Chernov, P.V. Terentyev has been for a long time the recognized leader of the Soviet batracho-herpetology.

The important scientific merits of P.V. Terentyev were duly recognized by many scientific institutions and organizations. He was Fellow of the Leningrad Society of Naturalists and of the Moscow Society of Nature Investigators, Honory Member of the Herpetologists' League, Fellow of the American Society of Ichthyologists and Herpetologists, Fellow of the Society of of Evolution, and a corresponding member of the Polish Academy of Sciences. Herpetologists of all the world will forever thankfully remember this remarkable naturalist.

RECENT DEATH

We hear, with great regret, that CHARLES E. SHAW, longtime Curator of Reptiles and more recently Assistant Director of the San Diego Zoo, died of cancer on 2 June 1971.

CURRENT HERPETOLOGICAL TITLES, XVI: 1970 - 1971

Herpetological Information Search Systems
American Museum of Natural History
New York, N. Y. 10024

We have brought to your attention more than 13,000 current titles in the pages of this journal to date.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any current paper (e.g., 1970-1971) that is concerned with a member of a Recent order of amphibians or reptiles.

HERPETOLOGICAL REVIEW has appeared bimonthly, beginning in 1971. This means that the titles published here will be even more current. We hope that the added numbers will serve to reduce the titles-per-issue to a more manageable number.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This list contains titles of books and articles that have come to our attention during the period 1 April through 21 May 1971. Periodical title abbreviations follow the American Standard for Periodical Title Abbreviations Z 39.5-1963 (American National Standards Institute, Inc., New York).

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and L. Greene. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. Dr. Robert W. Winter provided us with translations of titles, abstracts and papers from Slavic languages. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

Members of the Herpetology Department and the Library staff of the Museum have continued to aid our efforts. No commercial computer service yet offers all of the facilities that we need and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 32 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

HERPETOLOGISTS' YEARBOOK

The HERPETOLOGISTS' YEARBOOK for 1971 is in preparation and will be issued in the fall of this year. The Yearbook is a new idea in the field. Besides reviewing the status of special subjects on amphibians and reptiles, it will provide basic data on the biology and classification of these animals. This information, culled from the material retrieved and consolidated by the Genera of Reptiles Project (HISS) at the American Museum of Natural History, will be consulted on almost a daily basis by anyone who is interested in amphibians and reptiles. This first annual issue will contain hundreds of important items of information on these animals. We expect future issues to grow into a regular almanac of herpetology.

- A major section will present basic information on amphibians and reptiles: classification, longevity, critical temperatures, fecundity, and sizes. An up-to-date Checklist of the species of amphibians and reptiles in the United States and Canada will be included -- the first since K.P. Schmidt's in 1953.

- A "Current" section will include a Calendar for Herpetologists, information on college courses in herpetology, sketches of herpetological societies and herpetological collections, the status of endangered amphibians and reptiles, and perhaps of greatest interest, a Directory of Living Herpetologists.

- Special review articles will summarize the current knowledge of amphibian and reptile chromosomes, will present a taxonomic arrangement of North American snakes, and reviews of other subjects.

- Some outstanding portraits of amphibians and reptiles will be presented.

- American Standard abbreviations for more than 1,000 journals that publish information on amphibians and reptiles will be given.

- And each of these sections will be indexed thoroughly and fully referenced.

- A NOTE TO ADVERTISERS.

  The Yearbook will carry advertisements that are of interest to its audience. For information on rates, write the Editor at the address below.

[ ] Special pre-publication subscription to members of the Society for the Study of Amphibians and Reptiles, and of the Herpetologists League
@ $8.00..... $_____

[ ] Pre-publication subscription rate to INSTITUTIONS and others
@ $10.00..... $_____

I enclose a check for a total of..... $_____
Please make check to "AMNH Genera of Reptiles."

[Prices after December, 1971, will be $12 to individuals; $15 to institutions.]

Williston's
Osteology of the Reptiles

A classic account of the osteology, classification and evolution of reptiles, both fossil and living, by the leading reptilian paleontologist of his day. This important book is still indispensable to anatomists, paleontologists and students of reptiles in general, not only for the careful descriptions of reptile skeletons and definitions of families, but for the numerous drawings as well. The book was originally published by Harvard University Press in 1925 (314 pages, 191 illustrations), but it has long been out-of-print and virtually unobtainable. This reprint includes a new preface by Claude W. Hibbard and an index. Part of the cost of this book is being privately underwritten in memory of Walter R. Moberly which allows these reduced prices.

Prices

SSAR members before publication of the book
$2 paperbound $4 clothbound

Institutions; Individuals after publication
$6 paperbound $8 clothbound

Gray's
Zoological Miscellany

This journal, published privately in several parts from 1831 to 1844 by John Edward Gray, is one of the rarest yet taxonomically important natural history periodicals. About half of the pages are devoted to amphibians and reptiles including synopses of the vipers, rattlesnakes, and boids, and the original descriptions of dozens of new species. Included are species from all parts of the world, such as the tuatara. Other papers deal with mammals (2 articles), birds (17), fishes (7), and invertebrates (18). This reprint comprises the entire series (86 pages, 4 plates) and includes a new introduction and biography of Gray by Arnold Kluge and a table of contents.

Prices

SSAR members before publication of the book
$4 paperbound $6 clothbound

Institutions; Individuals after publication
$8 paperbound $10 clothbound

Both books are to be published in fall 1971. Please circle editions desired and send with payment to Dr. Henri C. Seibert, Publications Secretary, Society for the Study of Amphibians and Reptiles, c/o Morton Hall, Box HR, Ohio University, Athens, Ohio 45701, U.S.A. Make checks payable to "SSAR." Receipt sent on request only.

SOCIETY MEMBERSHIPS AND SUBSCRIPTIONS -- 1971

Though their numbers are increasing, it is still true that fewer than 60 per cent of the members of the HERPETOLOGISTS' LEAGUE belong also to the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES. And less than two-thirds of the members of the latter society also belong to the Herpetologists' League. We believe that each of the societies has something important and unique to offer the members of the other. In the interests of a greater combined membership of persons interested in amphibians and reptiles, we invite the members of each society to also join the other.

To ease this process, we offer the "easy-form" membership applications below.

THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

This young society (a 1967 outgrowth of the OHIO HERPETOLOGICAL SOCIETY) offers a number of different publications on amphibians and reptiles.

Its regular publications include the semi-annual JOURNAL OF HERPETOLOGY (about 200 pages per year), the bi-monthly HERPETOLOGICAL REVIEW (about 225 pages per year), and a series of FACSIMILE REPRINTS IN HERPETOLOGY, which is now devoted to reprints of G. A. Boulenger's contributions to American herpetology (about 100 pages per year). In 1971 the Society also assumed sponsorship of the CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES. Besides these publications, the Society issues a number of SPECIAL REPRINTS each year (see the back of this page for examples).

Membership is open to anyone interested in amphibians and reptiles. All classes of members receive the J HERPETOL, HERPETOL REV, regular issues of FACSIMILE REPRINTS, and all have the same membership privileges. The higher classes of membership aid the Society in improving and expanding its services to its members and to the field of herpetology.

[Please make check to "SSAR."]

THE HERPETOLOGISTS' LEAGUE

The Herpetologists' League is the elder and the larger of the two societies. It was established in 1936, when the journal HERPETOLOGICA (now in its 27th Volume) began publication.

HERPETOLOGICA appears quarterly, and will publish some 500 pages of papers on amphibians and reptiles this year. By arrangement with the SSAR, the Members and Fellows of the League also receive HERPETOLOGICAL REVIEW, beginning this year.

Anyone with an interest in herpetology is eligible for membership in the Herpetologists' League. The Fellows, who hold the voting rights in the League, are elected by the Executive Council, "on the basis of their contribution to the science of herpetology."

The Members receive HERPETOLOGICA, to which they can submit manuscripts for publication. They may also attend the Annual Meeting, which usually is held in conjunction with the AAAS meetings.

ANNUAL MEETING
THE HERPETOLOGISTS' LEAGUE
co-sponsored by
THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
Philadelphia, Pennsylvania
28-29 December 1971

CALL FOR PAPERS

Because of the large number of eastern herpetologists and the interest in the report of the "Amalgamation Committee", which will be presented there, we expect this co-sponsored meeting to be a large one. It is for this reason, and to avoid later problems with possible mailing delays, that we are making the call for papers so early. If you intend to present a paper, please respond before the deadline.

Ordinarily we would expect an author to present no more than one paper, nor to request more than 15 minutes for its presentation. Exceptions will be considered, however.

An abstract of no more than 200 words must accompany this form to qualify for inclusion in the program (see other side). If an abstract is not received, the paper will be treated as a "title only" contribution.

PLEASE NOTE THE DEADLINE: 1 OCTOBER 1971
(SEE OTHER SIDE FOR ADDRESS)

(PLEASE PRINT OR TYPE)

TITLE: _____

_____

AUTHOR(S): _____

_____

COMPLETE MAILING ADDRESS OF THE FIRST AUTHOR:

Is presentation of a paper a requirement for your attendance at the meeting? _____. If yes, does this mean that you will not receive funds or time for travel if your paper is not on the program? _____.

A B S T R A C T F O R M

Please type the final copy of your abstract in the form provided below. Use the format indicated in the sample: AUTHOR(S) in capitol letters; (institution) abbreviated in parens; and title. The allotted space is adequate for a 200-word abstract.

TILLEY, STEPHEN G. (Smith Coll.). Life history and population structure of Desmognathus ochrophaeus inhabiting wet rock faces.

Populations of the salamander Desmognathus ochrophaeus inhabiting wet, vertical rock faces in the vicinity of Mt. Mitchell, North Carolina were sampled and information on size and age at maturity was compiled. Site at maturity was found to increase with increasing elevation and smaller size than individuals inhabiting rock faces at 5025 and 3550 feet elevation yielded sample sizes sufficient to permit determination of age at maturity and juvenile growth rates for two populations. In the population above 3550 feet elevation, which in turn are attained by delaying sexual maturity about one year relative to its occurrence in the lower population. The juvenile growth rates of the two populations are similar to one another and to those estimated for nearby woodland populations.

USE A CLEAN TYPEWRITER AND GOOD RIBBON. This copy will be offset directly for the published abstract.

An abstract is an abbreviated, accurate representation of a presentation. Make the abstract as informative as possible, so that readers may decide, quickly and accurately, whether they need to obtain additional information. Do not include information given in the title. State the purpose, methods, results, and conclusions, either in that order or with initial emphasis on findings (results and conclusions). Make sure that the taxa of the animals studied are indicated either in the title or the abstract.

Make the abstract self-contained, since it must be intelligible without further information. Be concise without being obscure; retain the basic information and tone of the presentation.

Write most abstracts in a single paragraph. Normally employ complete, connected sentences, active verbs, and the third person. Use nontextual material such as short tables and structural formulas only when no acceptable alternative exists. Employ standard nomenclature, or define unfamiliar terms, abbreviations, and symbols the first time they occur in the abstract.

KARYOTYPIC VARIATION AND RELATIONSHIPS OF THE CALIFORNIA LEGLESS LIZARD ANNIELLA PULCHRA GRAY (REPTILIA: ANNIELLIDAE)

Robert L. Bezy & John W. Wright

Three taxa (Anniella p. pulchra, A. p. nigra, and A. geronimensis) are currently recognized in the family Anniellidae (Wermuth, 1969). We here report karyotypic differences between populations of A. p. pulchra and A. p. nigra, and discuss the relationships of the family Anniellidae as suggested by karyotype information.

MATERIALS AND METHODS:

Chromosomes were prepared by a colchicine, hypotonic citrate technique (see Lowe, Wright, and Cole, 1966) from 10 Anniella p. pulchra (6 male, 4 female) collected in the sand dunes of El Segundo, W. of Los Angeles International Airport, Los Angeles Co., California (LACM 64574-83) and 7 A. p. nigra (4 male, 3 female) collected at Asilomar, S. of Point Pinos, Monterey Co., California (LACM 63584-91). Most of the tissue samples were heterogeneous, and sources included spleen, small intestine, kidney, ova, and testes.

The karyotype described for A. p. pulchra is the modal condition seen among 189 (61 male, 128 female) mitotic metaphase spreads; that for A. p. nigra is based on 128 (65 male, 63 female) cells. At least 10 cells were studied from each of the 17 individuals, except for A. p. pulchra from which only 1, 2, and 6 cells were examined.

In counting the number of chromosome arms (n.c.a. or c.a.), only acrocentrics (A) were considered uni-armed, while metacentrics (M), submetacentrics (SM), and subtelocentrics (ST) were considered bi-armed, regardless of whether they were macrochromosomes (macros) or microchromosomes (micros).

KARYOTYPE DESCRIPTIONS:

The karyotype of the population of Anniella p. pulchra has a diploid chromosome number (2N) of 20, consisting of 8 pairs of macros and 2 pairs of micros (Fig. 1A). The macros fall into two fairly discrete size classes, each containing four pairs. The centromere positions of the 10 pairs of chromosomes (numbered from largest to smallest, as in Fig. 1A) are: 1, SM; 2, SM to ST; 3, SM (nearly ST); 4, ca. M; 5, A; 6, ST; 7, SM; 8, A; 9, A; 10, SM. The n.c.a. in this karyotype is 34.

All 7 specimens from the population of A. p. nigra have a 2N of 22, consisting of 16 macros and 6 micros (Fig. 1B). This karyotype differs from that of A. p. pulchra in that chromosome pair 5 is clearly ST rather than A, and there is an additional pair of micros (the smallest pair in the complement) which is A. The n.c.a. in this karyotype is 38.

DISCUSSION:

Anniella nigra was described by Fischer (1885) on the basis of a specimen thought to have been from San Diego, California, and said to differ from A. pulchra in having a darker dorsum, shorter tail, and longer preanal scales. Currently, nigra is considered a subspecies of A. pulchra occurring primarily on the Monterey Peninsula (Stebbins, 1966) and intergrading with A. p. pulchra along the coast of California, both to the south (Grinnell and Camp, 1917; Klauber, 1940) and the north (Miller, 1943).

One pericentric inversion and a loss (or gain) of a pair of micros is required to explain the karyotypic differences observed between the population of A. p. pulchra and that of A. p. nigra. In general, karyotypic differences of this magnitude have been found only between species or higher taxa. The taxonomic significance of these differences is tempered, however, by the report of Cole (1970) of somewhat comparable interspecific geographic variation in chromosome number and populational polymorphism in chromosome morphology in species of Sceloporus.

For the present, we consider the presence of pair 11 and the A condition of pair 5 to be the primitive karyotypic states in Anniella pulchra. From this hypothetical ancestral karyotype, that of A. p. nigra can be derived by a pericentric inversion (pair 5: A→ST), and that of A. p. pulchra by the loss of pair 11. The short arms of pair 6 appear slightly longer in A. p. pulchra, than in A. p. nigra, (Fig. 1), suggesting that a transfer of chromatin (via whole arm translocation) from pair 11 to the short arms of pair 6 may have preceded centromeric loss.

We intend to study further the morphological and karyotypic variation of lizards of the genus Anniella with emphasis on the reported areas of intergradation (A. p. pulchra x A. p. nigra) and sympatry (A. geronimensis and A. p. pulchra; Stebbins, 1954: 303). It is hoped that study of meiosis in "intergrading" populations may yield information on: (1) the homologue in A. p. pulchra of chromosome pair 11 of A. p. nigra; and (2) reproductive potential of hybrids (intergrades).

Matthey (1931) reported a specimen of "Aniella pulchra" from California as having a diploid chromosome number of 24 consisting of 4 very large V's, 4 large V's, 2 long rods, 6 short rods, and 8 very short round chromosomes. This suggests that a third karyotype may occur in Anniella pulchra.

When Gray (1852) described the genus Anniella, he placed it in the family Scincidae. Cope (1864) erected the then monotypic family Anniellidae which he considered closely related to the Scincidae. In his now widely accepted classification of lizards, Camp (1923) considered the anniellids to be closely related to the anguids. McDowell and Bogert (1954: 124) noted numerous osteological similarities between Anguis and Anniella, but chose to maintain the family Anniellidae because of its several peculiar skull modifications.

With the chamaeleontid Rhampholeon spectrum (see Matthey, 1957), Anniella p. pulchra shares the dubious distinction of having

FIG. 1. Karyotype of two populations of Anniella pulchra. A. A. p. pulchra (LACM 64583, ♂). B. A. p. nigra (LACM 64585, ♀). Lines equal 10 micra.

the lowest 2N (20) reported for lizards. The low chromosome numbers (20-22) combined with a moderately low n.c.a. (34-38) makes the karyotype of A. pulchra difficult to derive from that reported for any other group of lizards. This tends to strengthen the view that the degree of evolutionary divergence attained by Anniella is of a familial rank.

Published anguid chromosome numbers range from 30 (18 macros and 12 micros) to 48 (22 macros and 26 micros; Bury, Gorman, and Lynch, 1969). Karyotype studies of the junior author indicate that the n.c.a. in anguids ranges from ca. 40 to over 50. The anniellid-like Anguis fragilis has a 2N of 44, with 20 macros, 24 micros, and 48 c.a. (Margot, 1946). Because the karyotypes of anguids have higher numbers of chromosomes and chromosome arms, derivation of the Anniella karyotype requires many fusions (or chromosome losses) and pericentric inversions.

Scincid lizards on the other hand have lower chromosome numbers. Six New World species have a 2N of 26 (with 12 macros, 14 micros and 52 c.a.; DeWeese and Wright, 1970), while Old World skinks have been reported to have a 2N ranging from 24 (14 macros and 10 micros) to 32 (32 macros and 0 micros) with at least 36-46 c.a. (see Dutt, 1969). Resolution of centromere positions for micros of Old World skinks may increase this estimate of n.c.a. More recently, we have examined material which indicates that at least one species of the limbless acontine skinks has an even lower 2N (22, with 12 macros, 20 micros and 44 c.a.). Whether the similarities in chromosome number and in life-form between acontine skinks and anniellids indicate a phylogenetic relationship or the combination of morphologic and karyotypic convergence is a question requiring further study of both chromosomal and morphological evolution in these families. Certainly, their differences in both the number of chromosome arms and the relative numbers of macros and micros, indicate that at least some convergence (or parallelism) is responsible for their karyotypic similarity.

In the foregoing discussion, we have used the hypothesis that among lizards centric fusion rather than fission is the predominant mechanism of change in chromosome number. Although centric fission would reverse evolutionary directions, the relationships would remain constant. However, the specialized life-forms of acontine skinks and anniellids suggests that their low chromosome numbers are also derived (rather than primitive) states and that centric fusions (rather than fissions) are involved. We have discussed only those families (Anguidae and Scincidae) which have, on morphological grounds, been considered to be closely related to anniellids. The low chromosome numbers of the chamaeleontid Rhampholeon spectrum (see Matthey, 1957) and of five species of the spinosus group of Sceloporus (see Cole, 1970) we consider to be other examples of reductions in chromosome number that have occurred in other groups of lizards.

RANGE EXTENSIONS FOR GEORGIA AMPHIBIANS AND REPTILES

Charles H.Wharton & J.Donald Howard

Because details of the distribution and habitat of our herpetofauna are needed, we have documented range extension records supported by specimens from several institutions (abbreviated below). Unless otherwise noted, references to published ranges are those from Conant (1958, A Field Guide to Reptiles and Amphibians, Houghton Mifflin Co.) and Martof, (1956, Amphibians and Reptiles of Georgia, University of Georgia Press).

We wish to thank the following individuals for their assistance: Gerald Williamson, Savannah Science Museum (SSM); Lloyd Newberry, Armstrong State College; G. William Dopson, Jr., University of Georgia (UG); Susan Howard, Carol Wharton, and Tom French, Georgia State University (GSU); and William Leach for permission to publish information on his Floyd County cottonmouths.

Ambystoma talpoideum -- The range of the mole salamander is given as the entire Georgia Coastal Plain. The only Piedmont record is claimed by W.T. Neill (1947, COPEIA 4: 271-272, PUBL ROSS ALLEN'S REPTILE INSTITUTE 1(7): 75-96) who refers to an adult from Richmond County, 4 miles west of Augusta. We have taken 4 adults (GSU 1505, 22 Sept. 1970; GSU 1560, 3 Nov. 1970; GSU 1161, 12 July 1970; GSU 1664, 19 Jan. 1971) and one larva (GSU 1124, 14 June 1969) from the swamps of the Alcovy River, near Covington, Newton County, extending the range 130 miles WNW into the central Piedmont. The mole and the spotted salamanders (A. maculatum) are apparently not randomly distributed in an individual riverine swamp, but occur in relatively circumscribed "colonies."

Notophthalmus perstriatus -- Conant and John S. Mecham (1967, CAT AMER AMPHIB REPT) restrict the striped newt to southern Georgia west of a line between the Okefenokee (Charlton County) and Abbeville (Wilcox County). Gerald Williamson located a colony in a borrow pit in Bryan County close to the east side of the Ogeechee River. On 20 November 1970, with Williamson, we took 18 specimens (GSU 1607) from the submerged grass in the shallow pit in low sandhill country with scattered cypress ponds, extending the range 95 airline miles NE.

Desmognathus aeneus aeneus -- The Cherokee salamander is normally a montane form in Georgia. In the more southern Georgia mountains we have taken a number in Union County (GSU 74, 372, 724, 777) and Lumpkin County (GSU 40), and Gerhardt took it in Union County (SSM 69.1270) and Dawson County (SSM 69.1260) at altitudes approximately 3000 feet. W.T. Neill (1954, PUBL RES DIV ROSS ALLEN'S REPT INST 1(7): 75-96; COPEIA 1957(1): 43-47) summarized other records. Conant's range map suggests a continuous distribution between the Georgia Blue Ridge and its extension into Alabama. Several trips by the junior author appear to verify this. Three specimens (GSU 514) from Pine Log Mountain, Bartow-Cherokee County line, have typical Cherokee head patterns while a fourth (GSU 633) 1.5 miles E., has straight-edged, dorso-lateral lines, and a herringbone dorsal pattern as well. Another specimen (GSU 1011) from 60 airline miles SW Pine Log (Mount Zion, Carroll County) is similar, but lacks a herringbone pattern and has a nearly continuous dorsal median stripe. Two specimens (GSU 1175) from 5 miles SW Heflin, Cleburne County, Alabama, appear typical aeneus aeneus. Mount and Folkerts (1968, HERPETOLOGICA 24(3): 259-262, have a series (Auburn U. 6800-05) from 2.5 miles W Heflin. These localities are within or close to the Alabama extension of the Blue Ridge province as outlined by Duncan (1967, SIDA CONTRIB BOTANY 3(1): 76).

Pseudotriton montanus montanus -- The eastern mud salamander occurs in the eastern half of the Georgia Piedmont. There are 10 specimens from the Sandy Creek Swamp 3 miles N Athens, Clarke County (SSM 65.514, 69.793, 69.794). Our records suggest that it occurs W to Chattahoochee River. In support of this is a marginal record from the Alcovy River Swamps (GSU 1200 (1), 14 Oct. 1969), 3 specimens (GSU 987, 20 March 1969) from Morning Creek near Fayetteville, Fayette County and one specimen (GSU 971, 18 Jan. 1969) 11 miles SW Atlanta, Fulton County. There is one specimen (UG 398) from East Point, Fulton County.

Scaphiopus holbrooki holbrooki -- The spadefoot is supposedly absent from the Georgia Piedmont except from a tier of counties adjacent to the Fall Line in Hancock, Warren, McDuffie, Columbia and Lincoln Counties, where it was recorded by Neill (1957, ibid). There is a specimen (UG 661, 4 June 1959) from Greene County, in the next tier of counties northward. In February and March of 1966 Carl Gerhardt and Lloyd Newberry took a number of specimens (SSM 66.561 (3), 69.1242 (1)) breeding in ditches along the railroad track at Athens, Clarke County, following a heavy rainstorm.

Three additional specimens have been taken midway between the SE Piedmont records and the Ridge and Valley province in Gwinnett (GSU 700, May 1967), Fulton (GSU 942, 26 July 1967) and Douglas (GSU 461, 21 June 1965) counties. The Gwinnett and Fulton specimens were taken from sandy, alluvial soils of the Chattahoochee floodplain. The spadefoot's digging requirements may limit it to such environments in the Georgia Piedmont.

Hyla cinerea cinerea -- The green tree frog is usually considered to be a coastal plain species. There are 3 records for the Georgia Piedmont known to us. S. Lloyd Newberry (pers. comm.) encountered a huge breeding colony near Parkhaven, Jones County. Carl Gerhardt took 10 specimens calling at Clark Hill Reservoir, McDuffie County, at U.S. Highway 78 (SSM 69.1127, 19 June 1966). The most notable Piedmont record, however, is a series from a breeding colony 4 miles SE Greenville in Meriwether County, discovered by Carol Wharton (GSU 1489, 14 Aug. 1970 (4)).

Sternotheraerus minor minor -- The loggerhead musk turtle inhabits the southern portion of the Georgia Piedmont. Gilbert Helmken took a specimen (SSM 61.222) at Warm Springs, Meriwether County and we have 2 specimens (GSU 183, 22 July 1961) from 2 miles W Milner, Lamar County. Both of these are marginal records. Two specimens, (GSU 1510, 16 Aug. 1969), however, from the Alcovy River, Newton County, appear north of the published range.

Kinosternon bauri palmarum -- The striped mud turtle is unreported from coastal Georgia counties. We have one specimen (GSU 1300, 2 May 1970) from the coast, 3 miles NW Cox, McIntosh County, taken while crossing a narrow sandhill separating the Altamaha River Swamp from a cypress pond.

Clemmys guttata -- The range of the spotted turtle is the extreme eastern coastal plain border. Marginal records include a Candler County specimen (GSU 1603, 24 May 1970) from Stockinghead Creek Swamp, Metter, Georgia, and one (SSM 71.1623) taken 4 Sept. 1970 by Lloyd Newberry crossing State Highway 46, 3 miles E U.S. 1 near a big swamp bordered by sandhill-turkey oak, Emanuel County. A Twiggs County specimen (GSU 1584, 1 May 1970) was taken by the author and Zoology 445 class crossing Highway 129, 75 meters S of Shellstone Creek, extending the range 100 miles W.

Two spotted turtles were collected by Gerald Williamson sunning on a log in Effingham County. We visited this locality in November 1970. It is on a small tributary of the Ogeechee bordered by sand hill scrub. There was no moving water and the swamp floor was heavily silted. The Ogeechee lime (Nyssa ogeche) was the dominant tree.

Ophiosaurus attenuatus longicaudus -- The eastern slender grass lizard is unrecorded from the Blue Ridge province. We have a specimen (approximately 11.5 inches snout-vent length), (GSU 49A, 5 Sept. 1959) from Denton Creek at its junction with the Tallulah River 18 miles NW Clayton, Towns County, in an isolated mountain valley deep within the Blue Ridge.

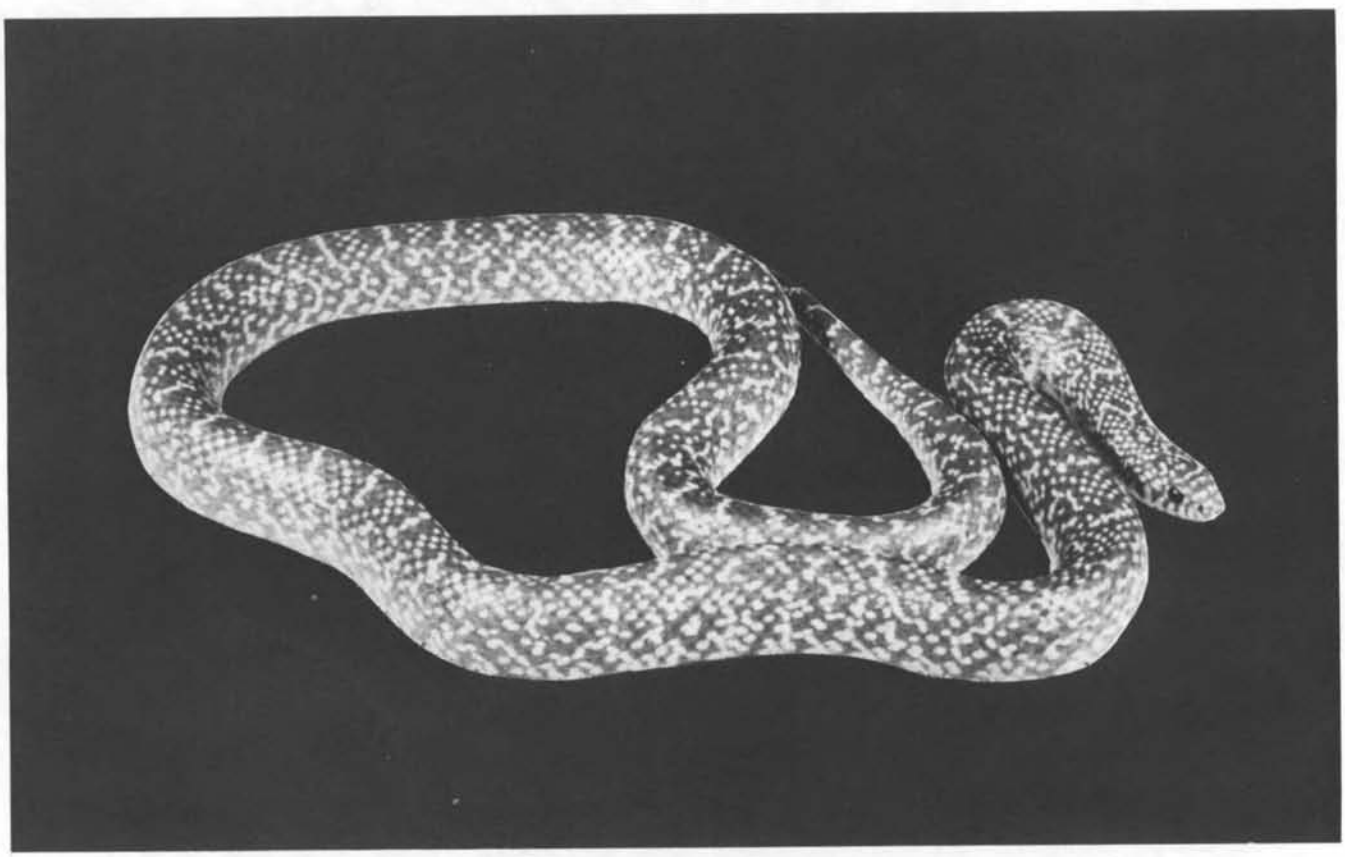
Natrix taxispilota -- The brown water snake ascends some Piedmont rivers. We have found it on the Flint, Ocmulgee and Oconee River systems. In 1940 I took a specimen below the mill dam at Milstead on the Yellow River, Rockdale County, the northern-most locality in the Atlanta vicinity. The most northerly Georgia record is from the Oconee River at Athens, Clarke County where Lloyd Newberry (pers. comm.), in 1965, captured several at night. In the southern Piedmont Mount and Schwaner (1970, HERPETOLOGICA 26: 76-82) list one specimen on a Chattahoochee tributary 6.1 miles E West Point

(AUV 6616) and Carl Gerhardt took one at the U.S. 78 bridge over Clark Hill Reservoir 19 June 1966 (SSV 69.1068).

This snake is common in beaverponds along the Flint River 15 miles S Atlanta (GSU 872 (3), 985 (1), 1006 (1)). One specimen (GSU 1511) is from Hard Labor Creek, Morgan County. Although this snake is normally a lover of quiet water, two immatures (GSU 1509) were collected by Tom French at White Shoals, Alcovy River, Newton County.

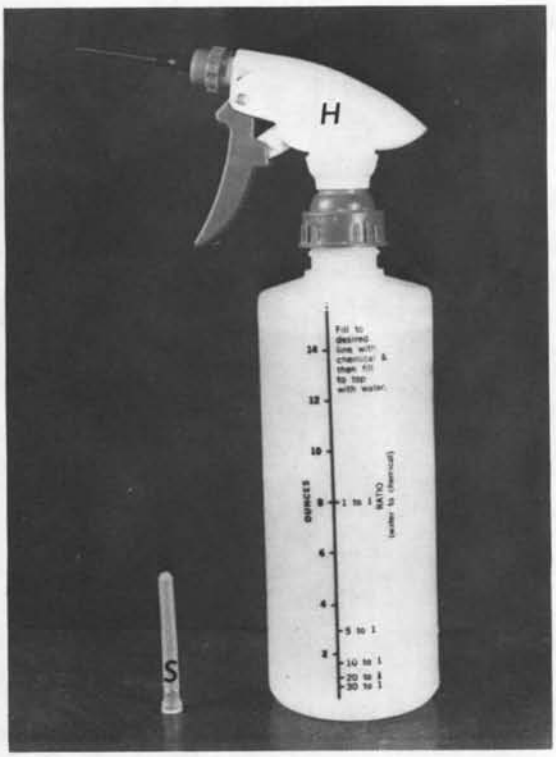
Elaphe obsoleta spiloides -- The grey rat snake ranges E to Central Echols County. We were surprised to capture two grey rat snakes in and near the Okefenokee Swamp, which is well within the narrow coastal range of the yellow rat snake (E. o. quadrivittata). One of these (GSU 87, 7 May 1960) was taken on a brush pile between Billie's and Minnie's Lakes, Charlton County and the other (GSU 946, 2 Dec. 1968) was taken at Fargo, Clinch County. It appears that this subspecies ranges from the Valdosta uplands through Fargo and up the peninsula of land (followed by State Road 177) to Billie's Lake near the center of the Okefenokee.

Cemophora coccinea -- The scarlet snake is rarely encountered in the Georgia Piedmont and is apparently absent from the mountains of the Blue Ridge. One reason may be the lack of connected deposits of sandy soils suitable for burrowing. There is a specimen (SSM 69.661) from a sandy road found by Otis Beauchamp in Banks County, near the headwaters of the Broad River. We have a specimen (GSU 198, 22 Dec. 1959) unearthed by bulldozer in a stream valley near Clayton, Rabun County, well within the Blue Ridge province.



Agkistrodon piscivorus -- For 30 years we have traced numerous false reports of cottonmouths in Georgia N of the Fall Line. Reliable reports indicate circumscribed and widely-separated pockets in the Piedmont. Neill (1947, HERPETOLOGICA 3: 203-205) has reported an isolated population in the swamps of Dry Fork Creek, Ogelthorpe and Wilkes Counties. There is also a specimen (UG 721) collected by Jack Connel 14 April 1951 from Fishing Creek, Wilkes County, the next major Savannah tributary SE.

On 7 August 1970, Carol Wharton collected a DOR cottonmouth on Ga. 18, 4 miles SE Greenville in Meriwether County. We visited this locality on 24 October. A long-time resident confirmed the presence of the cottonmouth on this tributary of Walnut Creek. Heavily cut-over and beaver pruned, the swamp supports a sweet gum (Liquidamber styriciflua), black gum (Nyssa sylvatica), sweet bay (Magnolia virginiana) complex, the latter forming nearly pure stands in places.



One of the most remarkable occurrences in northern Georgia is a concentration of cottonmouths on the Coosa River (elev. 600') and its coldwater tributary, Cabin Creek, Floyd County. The snakes were first reported by Noland Hess. Subsequently, J. William Leach (pers. comm.) took 40 specimens from Coosa River flood plain ponds near Rome, Georgia. Careful investigation by Leach of the Coosa River for 50 miles, and of streams both east and west indicate two localized pockets 15 miles apart. Three Floyd County specimens are at Georgia State (GSU 1608 (2), GUS 1609 (1)), 3 are in Leach's possession and 4 are at Shorter College.

We have a cottonmouth (GSU 48) from Annewakee Creek, Douglas County, .5 miles from its junction with the Chattahoochee. Several night collecting trips on Annewakee and nearby Bear Creek and Dog River failed to turn up other specimens. Since the Chattahoochee does not afford much typical habitat we conclude that this specimen was an introduction.

Atlanta, Ga. 30303

An amelanistic specimen of Lampropeltis getulus holbrooki. This unusual specimen from Baton Rouge, E. Baton Rouge Parish, Louisiana, is typically patterned with yellow spotting, but the normally black ground color is a very light yellowish tan. The absence of black pigment is also noted in the red eyes and tongue.

A NEW "SYRINGE" FOR INJECTING HERPTILES

Morris K. Jackson

The injecting of herptiles with a syringe and a hypodermic needle is often messy, time consuming, and, generally, objectionable. As a result, I have devised a simple inexpensive instrument which might be of some value to herpetologists. The "Grizzly (G) syringe" is a modified janitorial spray gun which has been adapted to a hypodermic needle (Fig. 1). The G-syringe, being constructed of unbreakable polyethylene, is light weight, non-leaking, and equipped with a volumetric scale which aids in preparing different concentrations of fixative. Assembly of the G-syringe is simple (Fig. 2): (1) remove nozzle (N) from head (H); (2) punch out plastic insert (I) from center of nozzle; (3) insert the hypodermic needle (NE) in the hole; and (4) replace nozzle on head. To be safe, replace protective sheath (S) on the hypodermic needle when not in use. Chlorox jugs and similar containers can also be used when greater volumes of fixative are needed.

I wish to thank Dr. Harley Reno and Miles L. Cook for assistance in this manuscript.

THE EGG-ALGA RELATIONSHIP IN AMBYSTOMA T. TIGRINUM

James D. Anderson, Dawn D.Hassinger and George H. Dalrymple

[In his covering letter for this article, Dr. Anderson states, "I have been concerned for some years that everyone assumes that this "symbiotic" relationship is beneficial to salamander development. My field experience always indicates that it is at best a fortuitous relationship and might even be detrimental under certain conditions in the field. I felt therefore that this should reach the people who might be making similar observations but ignoring them. Hopefully, it will also stimulate people to report the presence of the alga in various other species. I am convinced that it is not universally present, but unless people report the situation in their natural history papers, we really don't know." This introduction to the problem seems appropriate for the audience to which HERPETOLOGICAL REVIEW is addressed. -- Ed.]

In a series of laboratory studies, Gilbert (1942, 1944) reported higher survival, more rapid rate of development and larger size at hatching in eggs of Ambystoma maculatum harboring the green alga Oophilla amblystomatis. Lardner (pers. comm.) suggested that the symbiont was Chlamydomonas and indicated its occurrence in several species of amphibians. Although Gilbert (1944) and others reported a high incidence of the alga in A. maculatum masses in the field, there are no field studies indicating the degree of infestation, seasonal changes or benefits in a natural population.

During the winter and spring of 1969 we recorded the presence or absence of the alga in all egg masses (265) deposited by an isolated deme of Ambystoma t. tigrinum near Heislerville, Cumberland County, New Jersey. Three ponds (designated Front, Middle and Back) contained 234 masses, and 31 others were scattered in 6 other ponds. On three dates, between deposition and hatching we also determined stage of development and mortality in the masses and could therefore correlate frequency of infestation with the following: stage of development, pond, date, and mortality. Hassinger et al. (1970) described the life history and the habitat for this population and Anderson et al. (1971) discussed mortality in eggs and larvae during 1969.

The per cent frequency of algal infestation increased with the season and varied slightly between the three major ponds (Table 1). Both variations may be temperature effects. Middle pond thawed first but front pond was the shallowest and warmest as the season progressed. Prior to gastrulation the alga was absent (or at least not visible to the naked eye) but increased in frequency in subsequent developmental stages (Table 2; for a comparison of field designated stages with standard Harrison stages, see Hassinger et al. 1970). We also found a strong correlation between mortality and the presence of the alga. At any date all masses having zero mortality contained no algae and 97 per cent of masses with all eggs dead contained algae. Moreover, within a given stage of development (neurula) on a single date approximately half (49.2%) the eggs in masses containing the alga were dead whereas slightly more than a third (39.7%) were dead in masses without algae.

We noted no differences in rate of development or size of embryos in masses with or without algae. Thus we found no beneficial effects from the egg-alga relationship and in fact found a consistent correlation of the alga with higher mortality. From these field studies we were unable to determine whether the alga increased mortality or increased mortality enhanced conditions for the alga. The benefits demonstrated by Gilbert (1944) for A. maculatum eggs in the laboratory are not reflected in this field study on A. tigrinum.

Table 1. Percentage of egg masses harboring the symbiotic alga Chlamydomonas sp.

	28 January	15 February	9 March
Front	28.6	62.5	100
Middle	55.1	66.7	85.0
Back	23.3	86.7	86.9
All ponds	35.7	72.0	89.1

Table 2. Percentage of masses containing Chlamydonas at different stages.

Stage	% masses
cleavage	0
Blastula	0
Gastrula	12.5
Neurula	56.7
Tail Bud	76.3
Larval	97.1
Near Hatching	100

UNREVIEWED-UNEDITED COMMUNICATIONS

ESTIMATING LIZARD HOME RANGES

Frederick B. Turner

Milstead (1971) has commented on the simplicity of estimating home ranges of lizards occupying essentially plane surfaces, suggesting that there is no more to the task than drawing lines connecting various capture loci and determining the areas of the resulting polygons. I think there is considerably more to be said about this problem. I will comment first on the technical aspects of estimating home ranges, and secondly on the more general question of why home ranges should be measured at all.

To begin with, polygons based on recapture data can be drawn in a number of ways. One way is to connect the points so that the boundaries of the resulting polygons are not indented (convex polygons). Another method permits concavities in the boundaries of the polygons (minimum polygons), but with typical dispersions of capture loci many possible polygons can be constructed in this manner. More important is the sample size bias suffered by both polygon techniques. As more capture points are accumulated the animal's home range appears to become larger. This effect diminishes as the number of capture loci increases. Hence, the common practice of analyzing only home range data contributed by those individuals captured an arbitrary minimum number of times. If these problems have been recognized in the past, it is not apparent in the bulk of the literature pertaining to lizard home ranges. Both techniques have been employed, and the sample size bias either swept under the table or ignored. In my view, most of the home range data published for lizards are of little meaning as they stand.

Some improvement has been effected by the adoption of methods without sample size bias (Calhoun and Casby, 1958; Jennrich and Turner, 1969). The older of these techniques estimates circular home ranges, the radii of which ("recapture radii") are estimated from the dispersion of capture loci. Home range estimates derived in this manner are not biased by sample size, but are biased if the home range is not really circular. The first use of this method with lizard data was by Jorgensen and Tanner (1963). Tinkle later used this technique and 1) confirmed empirically the absence of sample size bias, and 2) discovered that home range estimates predicated on polygons were much smaller than those estimated from recapture radii (Tinkle, 1967: 98). However, if polygon estimates are corrected for bias, and if the home ranges are really circular, estimates derived by the two methods are similar (Jennrich and Turner, 1969; Turner et al. 1969).

It would obviously be advantageous to escape the restriction of circularity imposed by the Calhoun and Casby method, and this may be done using a technique based on the determinant of the covariance matrix of the capture loci (Jennrich and Turner, 1969; Mazurkiewicz, 1969). This method estimates elliptical home ranges (or circles, if both axes are identical), and in a manner free of sample size bias.

One difficulty not yet faced by those using either recapture radii or ellipses is that both of these methods assume bivariate normal distributions of activity. With the Calhoun and Casby method the bivariate distribution must also be circular. In either case the underlying probability distributions assume diminishing frequencies of utilization with distance from the home range "center." Perhaps some lizards actually distribute their spatial utilization in this manner. However, it is unlikely that strongly territorial lizards use their available space in this way. I do not know what the utilization distribution would look like, but it would almost certainly involve relatively higher probabilities of occurrence at the home range periphery. A tendency in this direction would be represented by a uniform distribution involving equal utilization of all parts of the individual's range. The same problem would arise in examining the apparent home ranges of animals occupying an enclosure if their activities brought them into frequent contract with the fence. The circular and elliptical methods of estimating home ranges are statistically pleasing in their lack of sample size bias, but they are realistic only to the extent that the assumed utilization distributions (bivariate normal) conform to reality. The nature of these distributions has never been investigated with lizards.

Why do we measure the home ranges of lizards? What questions are involved? By and large, the home ranges of lizards have been measured simply "because they are there." But these estimates need to contribute to the solution of some specific problem, or to the understanding of particular ecological processes. The relationship of home range size to energy requirements has been questioned by McNab (1963) and Schoener (1968), and while one may not wish to view these papers as definitive they certainly have the merit of posing a question which seems susceptible to testing. It has been suggested by White (1964) that home ranges may fluctuate inversely with population size, and Tinkle's data on male Uta seem to support this idea (Tinkle, 1967). Whether this is true among non-territorial lizards has not been explored to my knowledge. If these questions are not appealing, others undoubtedly exist (e.g., see Siniff and Jessen, 1969). In any event it seems to me that the questions to be posed and the techniques devised to answer them have progressed beyond the simple use of scissors and paper.

I thank Robert Jennrich for several clarifications of the text.

CARIBBEAN

RESEARCH

Fairleigh Dickinson University has announced the opening of a WEST INDIES LABORATORY on St. Croix, U. S. Virgin Islands. The multidisciplinary laboratory occupies an eight acre tract facing Tague Bay. Facilities include teaching laboratories and classrooms, research laboratories, darkroom, chemical storeroom, library, cold-storage room, outdoor saltwater aquaria, and fish pens. During the first summer session (18 July to 21 August) courses in marine ecology, marine invertebrate zoology, geological oceanography, and marine organisms and sediments will be offered. The second summer session schedule (22 August to 11 September) includes a course in terrestrial ecology of tropical vertebrates. The laboratory facilities are available to visiting groups and independent investigators, by application to Dr. H. Gray Multer, West Indies Laboratory, Fairleigh Dickinson University, Madison, New Jersey 07940.

JOS. J. SCHALL (Department of Zoology, University of Rhode Island) is planning to conduct a field study of Cnemidophorus lemniscatus arubensis on Aruba, Netherlands Antilles. He will be in the field from September 1971 through January 1972, and plans to concentrate on factors influencing the local distribution of the species on Aruba.

CHAIM KROPACH (Queens College, N.Y.) has completed a year's field study of the seasnake, Pelamis platurus, in the Gulf of Panama. Among other things he studied the food habits and feeding behavior, reproductive biology and population structure, relative densities and distribution in Panama Bay, and the effect of this snake on economically-important marine species. He also evaluated the danger of this snake to man.

The study is to be used toward fulfilling the requirements for a Ph.D. degree. It was supported in part by the Smithsonian Research Foundation and the Society of the Sigma Xi.

MEETINGS AND SOCIETIES

CALENDAR 1971

19-22 August....SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES, Annual Meeting, Univ. New Mexico, Albuquerque (cosponsored by the HERPETOLOGISTS' LEAGUE).

29 August - 4 September....AMERICAN INSTITUTE OF BIOLOGICAL SCIENCES, Annual Meeting, Colorado State Univ., Fort Collins.

1-4 November....SOCIETY OF VERTEBRATE PALEONTOLOGY, Annual Meeting, Washington, D.C. (with GSA).

28-29 December....HERPETOLOGISTS' LEAGUE, Annual Meeting, Philadelphia (with AAAS; cosponsored by the SSAR).

CALENDAR 1972

June.....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Boston.

July.....SALAMANDER SYMPOSIUM, Highlands Biological Station, North Carolina.

October...Combined Meeting: HERPETOLOGISTS' LEAGUE AND SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES, University of Oklahoma Biological Station, Lake Texoma.

INDIVIDUALS AND INSTITUTIONS

The private herpetological collection of COLEMAN J. GOIN has been deposited in Carnegie Museum, Pittsburgh, Pa. This collection consists of over 850 frogs, principally from Colombia, Suriname, Bolivia, Venezuela, and other parts of South America. Included are numerous specimens reported in "Frogs of Colombia" and in a forthcoming review of the tree frogs of Suriname (Annals of Carnegie Museum, in press). The collection also contains type-specimens of several species described by Cochran and Goin in "Frogs of Colombia."

ROGER CONANT (Philadelphia Zoological Gardens) received an honorary doctorate (ScD) from the University of Colorado at its Spring Commencement.

MARLIN PERKINS (St. Louis Zoological Gardens) received an honorary doctorate from the University of Missouri.

DAVID B. WAKE (U. California, Berkeley) will become Director of the Museum of Vertebrate Zoology this year.

KRAIG K. ADLER (U. Notre Dame) received the Thomas J. Madden Teaching Award for his outstanding classroom teaching.

ROBERT E. GORDON (U. Notre Dame) was appointed to the newly created position of Vice President for Advanced Studies, which combines the previous functions of the vice president for research and sponsored programs and the dean of the Graduate School.

STEVEN J. ARNOLD (U. Michigan), who is finishing his PhD dissertation ("The evolution of courtship behavior in salamanders"), will go to U. California, Berkeley, on a postdoctoral program with David Wake.

JANE A. PETERSON (U. Chicago), who is finishing her PhD dissertation on chameleon anatomy, will go to U. Michigan on a postdoctoral program with Carl Gans.

JEFFREY W. LANG (U. North Dakota) now finishing his MS thesis, will go to the U. Minnesota for his PhD work.

ARNOLD G. KLUGE (U. Michigan) has received a Guggenheim Fellowship for 1971-72, to study the reptiles of New Guinea and Australia.

DAVID S. SNYDER (U. Notre Dame) now finishing his PhD program ("Function of brooding behavior in the Green Salamander, Aneides aeneus"), returns to his position as Associate Professor of Biology, Austin Peay State University, Tennessee.

DOUGLAS H. TAYLOR (U. Notre Dame) will go to Miami U. (Ohio) as Assistant Professor of Zoology.

HERPETOLOGY AT THE UNIVERSITY OF RHODE ISLAND

Herpetological activities at URI have been increasing in recent years. In addition to the herpetology course taught this spring by Dr. Herndon Dowling, Adjunct Professor of Zoology, a number of herpetological research projects are underway. Recent Ph.D. theses include:

1970. ROBERT W. GUIMOND: Aerial and aquatic respiration in four species of paedomorphic salamanders: Amphiuma means means, Cryptobranchus alleganiensis alleganiensis, Necturus maculosus maculosus and Siren lacertina.

1971. JOHN H. SONGDAHL: The role of the parapineal in oxygen consumption cycles in the blue scaly lizard, Sceloporus cyanogenys (Cope).

1971. PAUL M. McILVAINE: Infrared reception in boid snakes.

1971. ORLANDO DeLUQUE: Oxygen dissociation curves of amphibians from different habitats.

Current graduate students and their thesis topics are:

Ph.D. MARK I. CONLEY: Effect of thyroxine, photoperiod and environmental temperatures on daily changes in metabolic rates of the toads Bufo boreas and Bufo marinus.

Ph.D. THOMAS L. DOTY: Competitive interactions of Ambystoma.

Ph.D. TERRY E. GRAHAM: Thermal ecology of the painted turtle, Chrysemys picta picta (Schneider).

M.S. THOMAS A. CAPRARO: Radiation tolerances of amphibians.

M.S. ANNE M. FORBES: Rare earth metabolism in Chelonia mydas.

M.S. JOSEPH J. SCHALL: Ecology of Cnemidophorus on Aruba.

M.S. SILAS C. WADE: Feeding behavior of slider turtles.

M.S. THOMAS G. ZACCONE: Karyology and relationships of some xenodontine snakes.

Dr. C. ROBERT SHOOP is conducting research on the population dynamics of local Ambystoma species, the biology of amphibian larvae, and orientation of amphibians and reptiles. Dr. Dowling continues his research into the systematics of reptiles, and bibliographic resources in herpetology. JAMES BRADLEY of the URI Computer Center has provided substantial aid in herpetological information retrieval.

The present ties between the Department of Zoology and the American Museum of Natural History allow the development of a particularly broad experience for herpetology students. Colloquium speakers this year included Drs. Walter Auffenberg (U. Florida), Kraig Adler (U. Notre Dame), Donald Tinkle (U. Michigan), and Henry Wilbur (Rutgers U.). Class trips in 1971 to the Savannah River Ecology Laboratory and to St. Catherine Island, Georgia, provided field experiences in different habitats. -- CRS.

C O R R I G E N D U M

A line was dropped from the legend to the figure in COLE, C. J. 1971CRF, HERPETOL REV 3(2): 37. It indicated that the line in the figure was equal to 10 micra.

MEMBERSHIP IN THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles.

Regular dues are $8 for persons living in the United States and Canada, $6 for those in other countries.
Sustaining Members pay $10, and Contributing Members $15.
Institutional Subscription, $16.

Write: HENRI C. SEIBERT
Treasurer, SSAR
Department of Biology
Ohio University
Athens, Ohio 45701

MEMBERSHIP IN THE HERPETOLOGISTS' LEAGUE

All persons interested in herpetology are eligible for membership.

Dues are $8 for Regular Members, $10 for Fellows. Institutional Subscription, $15.

Write:
HOBART F. LANDRETH, Secty-Treas.
Herpetologists' League
Department of Biology
Southwestern State College
Weatherford, Okla. 73096

SUBSCRIPTION TO THE CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

A loose-leaf series of species accounts of the amphibians and reptiles of the Americas, with special emphasis on those in the United States and Canada.

The Binder, Index Tabs, and all 100 accounts published to 1970 cost $18.00 to individuals, $20.00 to institutions. Subscription to the 25 accounts to be published in 1971 is an additional $5 for individuals, $7 for institutions.

CHANGES OF ADDRESS

Please inform us of your address changes as soon as possible. Each returned copy of HERPETOLOGICAL REVIEW costs us (and you) about 25 cents more in postage and considerably more in handling.

Send address changes directly to:

HERPETOLOGICAL REVIEW
Genera of Reptiles Project
American Museum of Natural History
New York, N.Y. 10024

We will see that changes go to the mailing lists of SSAR, Herpetologists' League, and CATALOGUE, as well.

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be type-written on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $23.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/8 inches (one column) or 9 1/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 12 3/4 inches). Line cuts are reduced about 25 per cent in processing. [See also the special instructions for "Un-reviewed."]

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

UNREVIEWED-UNEDITED COMMUNICATIONS

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions. Drawings should be made to widths of 3 1/2" (one column), 7 1/4" (two columns), or 11" (three columns). Each vertical inch of drawing takes up six lines of text. The three-column format allows about 270 four- to five-word lines (35 characters and spaces) per page.

Page charges are: $20 for a single page; $40 for the two-page maximum. Include an allowance for the title and author's name and five lines for the address and received date. Send a check for the proper amount with the manuscript. Or, if you prefer, we will bill you that amount for reprints.

S S A R

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

The SSAR encourages the acquisition of knowledge on amphibians and reptiles, and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communications between amateur and professional workers.

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society; they receive the JOURNAL OF HERPETOLOGY, HERPETOLOGICAL REVIEW, and issues of the Facsimile Reprint Series. They also receive reductions on the price of other Society publications. See the last page of this issue for information on membership and subscriptions.

E D I T O R I A L

The "Amalgamation Committee," described in HERPETOLOGICAL REVIEW 3(1) is steadily working on its report which will be presented at the Albuquerque Meeting, and again at the Philadelphia Meeting of the societies. The aim is to provide an easy transition from the two national herpetological societies (HERPETOLOGISTS' LEAGUE, and SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES) to a strong, truly international society which will be better able to provide its members, and the entire field of herpetology, with the publications and services needed by this active field. We are hopeful that such amalgamation might be possible at the proposed Lake Texoma Meeting of the societies in 1972.

Meanwhile, too, the SSAR is attempting to strengthen its relations with the various regional societies.

Among the many questions being considered by the Committee, the following are, perhaps, among the most important or controversial.

1) Aims and working structure of the Society;
2) Membership categories and dues structure;
3) Publication policies and subscription rates;
4) Officers of the Society and the mode of selection;
5) Carryover of present Officers and Boards during the transition period;
6) Standing Committees and their instructions;
7) Name of the unified Society;
8) Time-table of amalgamation steps.

We hope that as many members as possible will attend these important meetings. Whether you do or not, you should feel free to make your opinions known to the Committee, in person or by mail. Any Committee Member contacted will inform the others of your ideas. Please let us know. -- HGD.

HERPETOLOGISTS' LEAGUE

The Herpetologists' League is an international organization established by Major Chapman Grant in 1936. It is dedicated to furthering knowledge of the biology of amphibians and reptiles.

In 1970 it had 940 members and fellows, 24 life members, 10 honorary members, and 400 institutional subscriptions to its journal, HERPETOLOGICA.

All persons interested in herpetology are eligible for membership. Members receive HERPETOLOGICA (and now HERPETOLOGICAL REVIEW), to which they can submit manuscripts for publication. They may also present papers at the Annual Meeting.

See the last page of this issue for information on membership and subscriptions.

THE ALBUQUERQUE MEETING

By

William G. Degenhardt

The fourteenth annual meeting of the Society for the Study of Amphibians and Reptiles is being combined with a meeting of the Herpetologists' League this year. This combined meeting will be on the campus of the University of New Mexico in Albuquerque, New Mexico.

Located in the center of the "Land of Enchantment," Albuquerque is a city of 300,000 which boasts of its smog-free air and scenic backdrop of the 10,678-foot Sandia Mountains. Albuquerque's climate is mild, and the low relative humidity makes summer warmth pleasant. August is a time of occasional afternoon showers. However these are usually so brief that raincoats are rarely needed.

New Mexico has much to offer the biologist. The floral spectrum ranges from alpine meadows and mixed conifer forest in the mountains to grassland and Chihuahuan desert in the valleys. Herpetological exploration of New Mexico began relatively recently and has revealed many interesting forms, including such things as endemic salamanders, parthenogenetic lizards, and arid-adapted anurans.

Dozens of Indian communities quietly conserve pre-Columbian traditions. The Spanish people of New Mexico ruled the area for three centuries, and in the capital city of Santa Fe there are buildings still in use that were built before the Pilgrims landed. To the delight of connoisseurs, both Indian and Spanish cultures have richly flavored the art, architecture, and food of New Mexico.

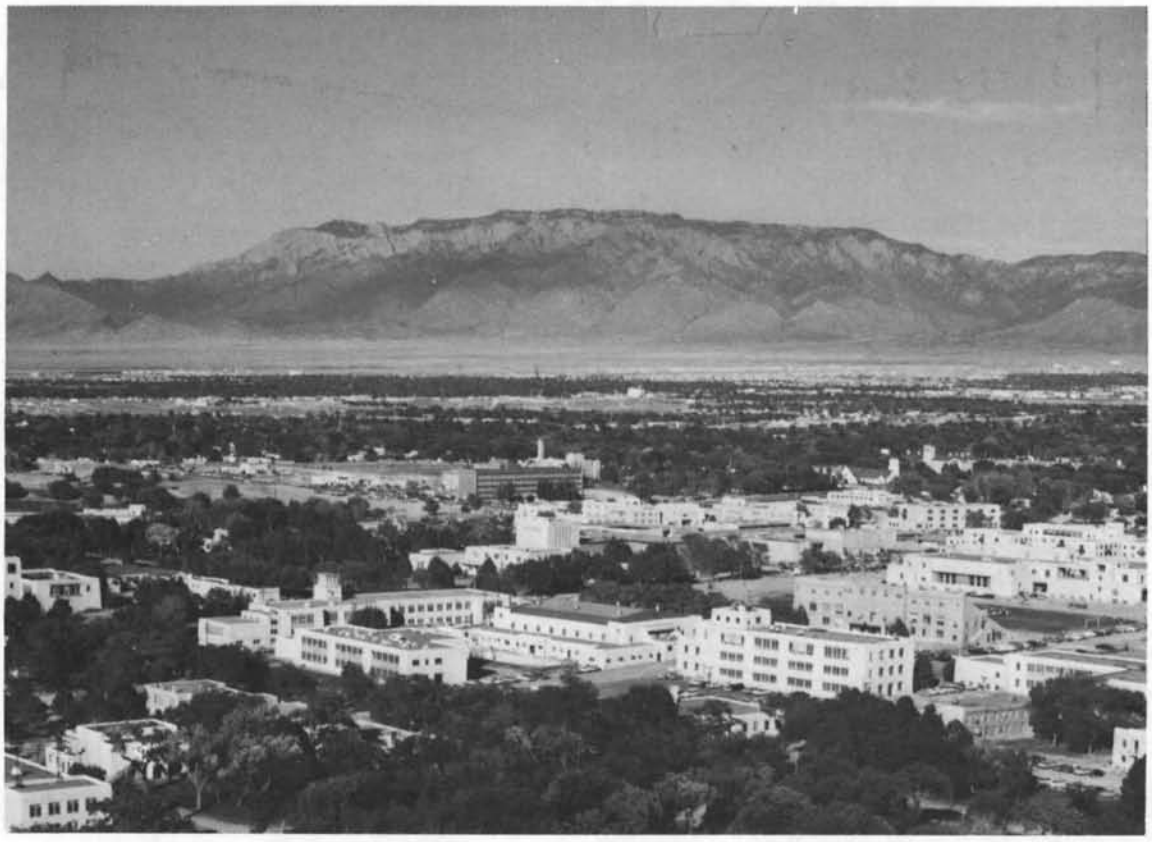

FIGURE 1. Over the UNM campus looking northeast towards the Sandia Mountains. Central New Mexico offers choice recreational and herpetological study areas.

In addition to four sessions of contributed papers, the meeting will include two sessions of longer, invited papers. Centered around this year's theme, the ecology of arid-adapted amphibians and reptiles, the sessions of invited papers will be chaired by Charles M. Bogert and will include: "Temperature regulation in desert amphibians and reptiles: past, present, and future studies" (Bayard H. Brattstrom, California State College at Fullerton), "A bioenergetic approach to food niche dimensionality in three sympatric species of spadefoot toads" (Arthur E. Dunham, University of New Mexico), "Evolution and biogeography of the southwestern herpetofauna" (Charles H. Lowe, University of Arizona), "Water and electrolyte balance of desert reptiles" (John E. Minnich, University of Wisconsin, Milwaukee), "Transient energy budget studies: their implications for analysis of behavior, physiology, and predator-prey interactions of desert reptiles and other animals" (Warren P. Porter, University of Wisconsin, Madison), and "Energy flow in southern Nevada populations of Uta stansburiana: a three-year analysis" (Frederick B. Turner, Philip A. Medica, and Bruce W. Kowalewsky, University of California at Los Angeles).

Lodging and meals will be available on campus; cost is anticipated at about $4 per person per night for rooms and $3.75 per day for meals. Social and sight-seeing activities are being planned for herpetologists and their families. Anyone interested in exhibiting photographs or other materials should contact the local committee as soon as possible. Also, some thought is being given to a book-journal-reprint "sell and swap."

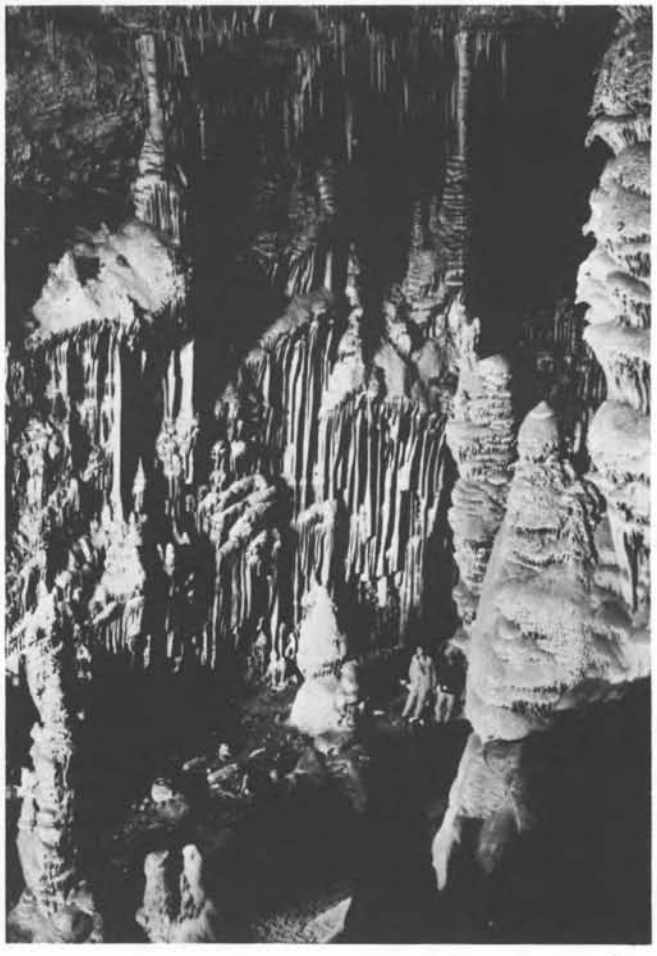

FIGURE 3. Carlsbad Caverns and hundreds of other caves attract tourists and spelunkers to the Guadalupe Mountains in southeastern New Mexico. This is the Entrance Room of Cottonwood Cave, one of the more spectacular.

FIGURE 2. Research facilities and exhibits will be on display in the UNM Biology Building (Castetter Hall). Of special interest are the greenhouses and herpetological collections.

All inquiries should be addressed to the chairman of the local committee:

GALAPAGOS TORTOISES, 1971

By Peter C. H. Pritchard

In the February 1971 issue of Herpetological Review, I outlined the survival prospects of several races of Galapagos tortoise. In January and February of this year, I was able to re-visit the islands, and to locate specimens of four more races of tortoise - the two northern and the two southern races on Albemarle Island, or Isabela, the largest island in the group and the only one with more than one race of tortoise.

Figure 1. G.e. elephantopus(adult male at the base of the east flank of Sierra Azul, Albemarle Island.

The tortoises of Volcan Wolf, which is the highest mountain in Galapagos and is situated at the northern end of Albemarle, are usually called Geochelone elephantopus becki. However, Rothchild's type specimen of Testudo becki, collected by Rollo Beck in about 1900, was taken on Cape Berkeley, a massive and precipitous mountain at the north-west tip of Albemarle, which is separated from Volcan Wolf by several miles of jagged lava, completely impassable to a tortoise. If the collection data are accurate, there are six, not five, isolated populations of tortoises on Albemarle, and, if it proves distinct, the Volcan Wolf population will have to have a new name. However, Cape Berkeley is rarely visited and almost never climbed, and we do not know if tortoises exist there today. The lower slopes of the mountain are exceedingly steep, but from a boat one can see high plateaus which could conceivably harbor tortoise populations.

Tortoise still exist on Volcan Wolf, and, since they come quite close to the sea both on the north coast and at Bank's Bay on the south-west side of the volcano, they may be found within only an hour or two's walk from the coast. Herndon Dowling found several of various sizes on the north coast a few years ago. I landed at Bank's Bay on January 21, 1971, and after crossing a mile or so of really hideous terrain found seven tortoises, all small to medium in size. This population appears to be reproducing quite successfully, as pigs and rats, both voracious predators on hatchling tortoises, are not present on this part of the island. The only introduced mammals on both the northern two volcanos of Albemarle are cats, and they are not plentiful. The Wolf tortoises are, morphologically, a strange mixture. The 'saddleback' shape shown by several races of Galapagos tortoise is only developed as maturity is approached, and tends to be most extreme in the largest individuals. However, the Wolf population shows both dome-shaped tortoises and good saddlebacks, the former perhaps outnumbering the latter, but neither shape seeming to show any relation to age, or even to sex. It is conceivable that a formerly isolated pure saddleback population on Volcan Wolf has been invaded within comparatively recent times by an influx of dome-shelled tortoises from Volcan Darwin to the south; this hypothesis assumes either that the two populations have not interbred, or that they have undergone secondary intergradation with a production of extreme as well as intermediate intergrades.

Tortoises are not as easy to find on Volcan Darwin as they are on Volcan Wolf. I ascended the volcano from Tagus Cove on January 22. Within an hour of leaving the sea I was in country obviously frequented by

FIGURE 2. Warden Arnaldo Tuzpina taking approximate measurements of a young G.e.guntheri near Cerro Grande on Albemarle Island.

tortoises, judging by the presence of numerous old pieces of dung, and the crumbling skeletons of two tortoises killed, probably by fishermen, some years before. However, I had reached about half way to the rim of the crater before finding a live tortoise, and that was only a small one, about fifteen inches long. A few hundred yards from the crater rim I came across five more tortoises, the largest being an adult female. Despite the low density of tortoises on the mountain, it is noteworthy that, of the six individuals found, in two cases tortoises were resting within about two feet of each other. Similarly, on Volcan Wolf, the first three tortoises found were chasing each other down a trail and were only a few feet apart.

I did not re-visit the thriving and abundant population of tortoises in the crater of Volcan Alcedo. However, I understand that the geyser on the southern part of the crater wall has dried up, depriving the tortoises of one of their few sources of standing water. Also, a fire burned over about ten per cent of the rim in 1970, but it appears that the tortoises in this area managed to escape, and new vegetation is already showing through.

FIGURE 3. James Island toroise, Geochelone elephantopus darwini hatching at the Charles Darwin Research Station.

The two tortoise populations on the southern half of Albemarle Island (Geochelone elephantopus guentheri and G. e. elephantopus) are much reduced from former times, this being a fertile, settled area and the site of a former penal colony. However, both subspecies still exist, and both are reproducing.

G. e. guentheri is now confined to an area between the eastern part of the rim of the crater of Sierra Negra and Cerro Ballena. About 150 have been marked by the resident wardens, almost all of which were immature; the average tortoise here is only about eighteen inches long. Nevertheless, no one has been able to locate a nesting zone. The tortoises are very thinly spread out, and in an entire days search in the tortoise area we only found two. This population is only a couple of hours' walk from the settlement of Santo Tomas, and tortoises are still occasionally killed by settlers. Feral mammals of various kinds are found in this area, but have not undergone any population explosion. In the course of our day's walk we found three goats, all of which we shot.

The southeastern volcano of Albemarle, Sierra Azul, can be reached on foot from Santo Tomas. The trail passes along the rim of the Sierra Negra crater, the second-largest crater in the world (Ngorongoro is larger). Unlike Ngorongoro, and unlike Volcan Alcedo, Sierra Negra is a sterile crater, harboring little except lichens; there is no shade, water, or food for tortoises, nor could tortoises ascend the very steep slope to the rim. The trail then passes through an area of lush grass, from which tortoises were exterminated by settlers. Tortoises are found on the east, south, and west slopes of Sierra Azul. A long tongue of lava, only about 45 years old, extends from the eastern side of the mountain almost to the south coast of the island, effectively dividing the range of G. e. elephantopus. Only a few tortoises now live on the eastern side of the lava, where feral pigs impede successful reproduction, but there is a good, and reasonably undisturbed, nesting zone within a few yards of the western side of the fresh lava. In the course of a day we found eight tortoises in this area, ranging in length from about ten inches to about 40 inches. We also found several old nests, some from which young had escaped, others with eggs containing mummified young, and one with a hatchling tortoise in the process of emerging. We also found a dead, intact hatchling about one foot from a nest; it had presumably been killed by exposure to the sun. For some reason eggs and hatchlings of this race are smaller than those of any other subspecies, even though the adults reach a large size. Feral mammals of various kinds roam Sierra Azul, and wild dogs in particular are a menace to tortoises not only of hatchling size but for several years afterwards. About 150 tortoises of this population have now been marked.

Tortoises are still found near the coast at at least two sites on southern Albemarle:

FIGURE 4. Hatchling G.e.porteri, hatched at the Darwin Station

near Cape Rose, and near Iguana Cove. Time did not permit me to visit either of these populations.

In January 1971 I was able to re-visit James Island, where a new trail has been cut to the 'pampas' in the highlands. This is a huge area of rolling lush grassland, with isolated hills, whose existence is hard to believe when one sees the desert-like lowlands of James. Jose Villa from the Darwin Station spent four months in this area in 1970, and raised the total of marked tortoises on the island to about 350; the present estimate for the entire population is around 500. Almost all are very large, old individuals, and males outnumber females. Villa shot about 1500 feral pigs during his stay on the island, but estimates that about 3000 remain. There are also an estimated 25,000 goats! However, for the time being there is food enough for the tortoises; it is more important to use one's valuable ammunition on pigs, which eat the hatchling tortoises. Two or three good nesting areas were located by Villa, and the eggs were transported to the Darwin Station, where by late February over sixty had already hatched.

FIGURE 5. One of the first Hood Island hatchling G.e.hoodensis breaking free from the egg at the Darwin Station

There is also exciting news about the prospects of the Hood Island tortoise. A captive group of a male and three females has been maintained at the Darwin Station for about three years, leaving a known male and two females on Hood Island. An expedition early this year to try and locate the male failed, but one of the two females on the island was found, and was brought back to the station. A total of 44 eggs was produced by the captive group last year, and when I left in late February six of these had hatched. In a recent letter from Peter Kramer, the new Director of the Station, I learn that they now have 16 healthy hatchlings of the Hood race. Dr. Kramer also mentioned that they have succeeded in breeding the Chatham Island race in captivity, up to now ten hatchlings (including two albinos) having been produced. The population on Chatham Island is not reproducing well in the wild, though 150 tortoises have now been marked and as many as 300 may exist. In future years it is hoped to bring Chatham tortoise eggs to the Station for artificial incubation and raising.

Twenty-five year-old Duncan tortoises (G. e. ephippium) were recently taken back to their native island, and appear to be adjusting well to their first taste of freedom; they are growing faster than a control group of nine of the same age still at the Darwin Station. Craig MacFarland and three wardens hiked up to the highlands of Duncan, each with five tortoises on his back; not only an arduous job, but a messy one, as those who have handled well-fed tortoises can verify! The total number of marked adult tortoises on Duncan still stands at about 105. Of the other population, 1338 have been marked on Indefatigable, and about 400 on Volcan Alcedo, Albemarle. However, no special effort is being made to mark the relatively safe populations on the three northern volcanos of Albemarle.

As readers of the Review may perceive, Herndon Dowling and I represent poles of pessimism and optimism as far as the future of the giant tortoises is concerned. It is true that the Darwin Station had to wait several months for a new Director; but most will agree that Dr. Peter Kramer, the new Director, was worth waiting for. Dr. Kramer is stepping up the frequency of goat-killing trips to Barrington Island; a party of wardens now visits the island every three weeks or so, to kill every goat they see. The population has now been reduced to a hard core of fifty or so, resident in a dangerously precipitous zone at one end of the island. If the goats can be completely eliminated, or even just kept down to their present numbers, the vegetation of the island will have a chance to recover. Dr. Kramer is also organizing trips to Bindloe Island, to eliminate the goats which appear to have been introduced to this island very recently. Goats are now so numerous on Abingdon Island that it will take a major - and very expensive expedition to eliminate them, or even thin them out.

It is also, regrettably, true that Beagle III has not yet arrived in Galapagos, and visiting scientists are still dependent on local fishing boats. However, it should be pointed out that Beagle II did not sink by accident, but was stripped of its fittings and sunk deliberately when it was deemed no longer seaworthy.

REGIONAL SOCIETIES PAGE

In previous issues of HERPETOLOGICAL REVIEW I promised to update the list of regional herpetological societies (H R 2(3)). Three such societies and one new publication have recently come to our attention. They are the Florissant Herpetological Society, The Florissant Turtle and Tortoise Society, The West End Reptile Club, and Volume 1, No. 1 of the Bulletin of the Philadelphia Turtle and Tortoise Club. Each is described briefly below.

FLORISSANT HERPETOLOGICAL SOCIETY (Gary R. Bloyd, 42 Radford Dr., Florissant, MO 63031). This is a small club of local amateur herpetologists -- something like a neighborhood club. It publishes a monthly bulletin on different general aspects of herpetology. Activities include snake hunts and field trips. It is strictly a local organization. (Bulletin nos. 1-26 were published in 1970; nos. 27-29 in 1971).

FLORISSANT TURTLE AND TORTOISE SOCIETY (Jim Selke, 1340 Layven Ave., Florissant, MO 63031). Another local group which publishes an irregular bulletin on different aspects of turtles and turtle-keeping.

SONS OF DAMBALLA (sound familiar?) was once part of the name of the Western Reptile Association. Arden Brame was kind enough to send us the early issues of their Bulletin. From these we learned that Damballa is the main deity in the Voodoo religion. Damballa in Africa was Chango, god of fire. Damballa became the main god whose spirit was housed in a snake. These people saw the ancient wisdom a snake seemingly possesses. Because it is considered the servant of Damballa, the snake is treated with reverence, and is protected and honored.

Bulletin #1 appeared in 1967, nos. 2-7 appeared in 1968. The same year the society changed its name to WEST END REPTILE CLUB. Bulletins 8-13 appeared under that name for the rest of the year. Nos. 14-19 were published in 1969 and 20-(?) in 1970.

Volume 1, no. 1. There is a new publication on the market, by the recently-established Philadelphia Turtle and Tortoise Club. It is a clear plastic - covered Bulletin in a ring binder. And all for $2.00 per year.

IUCN CROCODILE COMMITTEE MEETING
New York Zoological Park
15-17 March 1971

The participants included: Angus Bellairs, Robert Bustard, Robert Chabreck, Hugh Cott, Max Downes, Fred Hauptfuehrer, Rene Honegger, Wayne King, Fred Medem, James Oliver, Tony Pooley, James Powell, Moira Warland, Uthai Yangprapakorn.

Agenda Topics:

1. Talks on National and Regional situations. Reports on the crocodilians found in various countries.
2. Controlled breeding of crocodiles as a means of reducing pressure on wild populations.
3. Other items included: A Conservation program for crocodiles. National Parks and the Red Data Book. The Crocodile Foundation.
4. Crocodile Biology and Ecology.

The evidence presented at the meeting shows that all species of crocodiles are declining in numbers all around the world, with the exception of the American alligator. The reason the alligator is not declining is because of the recent protective legislation passed by the Federal, State and local governments. Special attention was called to the critically endangered status of the Apaporis River caiman of Colombia, which has become the subject of wide-spread hunting in the last two years, and the Cuban crocodile which may be lost through genetic swamping with the American crocodile, with which it shares the holding corrals in the Zapata Peninsula National Park in Cuba. At least two species, the Cuban crocodile and the Siamese crocodile are presently more abundant in captivity than in the wild. It is estimated that fewer than 200 wild crocodiles of any species remains in Thailand while over 11,000 are in captivity in the one crocodile farm there.

HERPETOLOGY COURSE AT NYU

A two-semester, graduate-level course in systematic herpetology, utilizing the resources of the American Museum of Natural History, will be taught by Herndon G. Dowling, Adjunct Professor of Biology, NYU, beginning Fall 1971.

Tentatively, the course will consist of two hours of lecture and two of laboratory work (evenings) each week, plus several field trips (4 credits per semester). The Fall Semester will be devoted to the study of reptiles, the Spring Semester to amphibians.

CURRENT HERPETOLOGICAL TITLES, 1970 - 1971

Herpetological Information Search Systems
American Museum of Natural History
New York, N. Y. 10024

We have brought to your attention more than 13,000 current titles in the pages of this journal to date.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any current paper (e.g., 1970-1971) that is concerned with a member of a Recent order of amphibians or reptiles.

HERPETOLOGICAL REVIEW has appeared bimonthly, beginning in 1971. This means that the titles published here will be even more current. We hope that the added numbers will serve to reduce the titles-per-issue to a more manageable number.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This list contains titles of books and articles that have come to our attention during the period 2 March through 31 March 1971. Periodical title abbreviations follow the American Standard for Periodical Title Abbreviations Z 39.5-1963 (American National Standards Institute, Inc., New York).

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and L. Greene. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. Dr. Robert W. Winter provided us with translations of titles, abstracts and papers from Slavic languages. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

Members of the Herpetology Department and the Library staff of the Museum have continued to aid our efforts. No commercial computer service yet offers all of the facilities that we need and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 31 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

A NOTE TO CATALOGUE SUBSCRIBERS

Subscribers to the CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES have received the first three issues of this year's HERPETOLOGICAL REVIEW without charge. We hope that you have enjoyed this contact.

However, unless you are a member of one of the herpetological societies (H L or SSAR), you will not receive future issues of this publication. If you are not presently a member, we suggest that you join either (or both) of these organizations. Dues are $8 for either Society; separate subscription to H R, if you do not want to join, is $5.

Information on the societies is found on page 46. Instructions for joining are on page 60.

A QUESTIONNAIRE FOR HERPETOLOGISTS

To aid the Editor of HERPETOLOGICAL REVIEW in visualizing his audience, and to help the Amalgamation Committee in determining needed services and in predicting membership, we ask that everyone with an interest in amphibians and reptiles fill out the following questionnaire. The information will be used only in statistical fashion and for identifying your field of interest. If any of your associates are interested in this field but do not receive H R, please xerox him a copy or have him send to us for another.

1. Name:_____ 2. Address:_____

_____

_____

3. I would class myself as a:
   - __ Student (please indicate level)_____
   - __ Zoologist - herpetologist
   - __ Zoologist - non-herpetologist (please indicate field)_____
   - __ Physician
   - __ OTHER (please indicate)_____

4. My specific interest in herpetology is:_____

_____

(Please be precise: "Ecology of Cnemidophorus," "Taxonomy of ranid frogs,"etc.)

5. I belong to (subscribe to) the following national societies (PUBLICATIONS):
   - __ Society for the Study of Amphibians and Reptiles (J HERPETOL)
   - __ Herpetologists' League (HERPETOLOGICA)
   - __ CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES
   - __ American Society of Ichthyologists and Herpetologists (COPEIA)
   - __ American Institute of Biological Sciences (BIOSCIENCE)
   - __ American Association for the Advancement of Science (SCIENCE)
   - __ OTHER (please list):

_____

6. I belong to the following regional societies:
   - __ Philadelphia Herpetological Society
   - __ New York Herpetological Society
   - __ Chicago Herpetological Society
   - __ OTHER (please list):_____

7. Of the various features in HERPETOLOGICAL REVIEW, please rank them in terms of your interests: (use numerals 1 - 6)
   - __ Major Articles
   - __ Current Herpetological Titles
   - __ Unreviewed - Unedited Publications
   - __ Regional Societies Page
   - __ Other (please list)_____

8. What new features would you like to see included ?

Moves toward amalgamating the SSAR and the H L are still in an early stages, and it is possible that amalgamation will not come about. However, the following questions assume that the two societies will join.

9. What name would you prefer for the society ? [Indicate 1st, 2nd, & 3rd choices.]
   - __ Society for the Study of Amphibians & Reptiles
   - __ Herpetologists' League
   - __ Society for the Study of Herpetology
   - __ Herpetological Society of America
   - __ OTHER (please list)
   - __ International Herpetological Society
   - __ The Society of Herpetologists
   - __ The Society of Herpetology
   - __ The Herpetological Society

_____

10. At present, members of the H L are paying $8 or $10, those of SSAR pay $8 or $15. A combined society would need a graduated dues structure to accomodate to the varying needs of its large membership. Three Classes of members have been suggested, each to receive substantially different publications and services. The member Classes may be something like the following. Please indicate which class you would probably choose.
   - __ Associate Member (Non-voting; receive HERPETOLOGICAL REVIEW only)..... $6.
   - __ Regular Member (Voting; receive H R, plus the journals of both societies)..... 15.
   - __ Professional Member (as Regular, plus other substantial benefits)..... 40.

11. Any additional comments ?

PLEASE RETURN BY 1 AUGUST TO:

UNREVIEWED-UNEDITED

TAXONOMIC RECOGNITION OF TRIPLOID *AMBYSTOMA* SALAMANDERS

James D. Lazell, Jr.

Uzzell's (1964) monumental work on the salamanders of the *Ambystoma jeffersonianum* complex resulted in recognition of four different sorts of salamanders: *A. jeffersonianum* (Green) and *A. laterale* Hallowell are distinct, bisexual species; triploid females associated with *jeffersonianum* were called "*A. platineum* Cope," and triploids associated with *laterale* were called "*A. tremblayi* Comeau." No theoretical discussion was presented to justify giving the unisexual, gynogenetically reproducing triploids rank as species. Maslin (1968) has provided a summary discussion of the taxonomy of uniparental organisms, but uses the phrase "sexual isolation" in a way that confounds gynogenesis and parthenogenesis - two very distinct modes of reproduction. Maslin is clearly implicit in his view that all uniparental forms result from interspecies hybridization; this is certainly the case with the triploid salamanders (Uzzell and Goldblatt, 1967). My own field work (Lazell, 1968, 1970) has brought the issues into sharp focus. The answers to five major questions are relevant here:

(1) *Do new species originate from interspecies hybridization?* The eminent botanist Stebbins (1950, p. 279) states "hybridization...is...by its very nature not a way of producing new morphological or physiological characteristics, and therefore of progressive evolution." Stebbins proceeds to cite various examples of hybrids that have been given names, in almost all cases eventually resulting in a ranking of parental forms as what we (and Stebbins) would regard as subspecies. In the genus *Viola*, and several others, however, Stebbins notes apparently full species resulting from interspecies hybridization. He notes (p. 287) "the evolutionary importance of such fertile hybrid derivatives depends on both their morphological characters and on the degree of fertility or sterility which is found when they are crossed back to their original parents."

Essentially, some forms of hybrid origin do qualify as full species, if they are capable of intrabreeding (as individuals, with each other), and incapable of interbreeding with their parental (or other) species. Species of hybrid origin, among plants at least, are rare; most hybridization does not result in the evolution of new species.

Except for parthenogens, no unequivocal or uncontested case of a species of hybrid origin exists in animals. Lorenz (e.g., 1952) has suggested in popular literature that the dog, *Canis familiaris*, is a form derived from hybridization between the wolf, *C. lupus*, and the jackal, *C. aureus*. No one known to me takes this very seriously, and the usefulness of regarding *C. familiaris* and *C. lupus* as distinct species in the first place is highly questionable. Examples of "species" of birds of hybrid origin are rampant. In all cases, the hybrids so described have proved to be either rare freaks, intergrades between forms properly regarded as subspecies, or hybrid swarms occurring in temporary habitats and not qualifying for species rank in terms of internal intrabreeding to the exclusion of parental interbreeding. Even in the most controversial cases, the hybrid forms lack any adaptively significant, inheritable innovations of their own; they are strictly combinations of parental characters. As examples, see Meise (1936) and Vaurie (1959, pp. 567-573), and works cited therein.

Johnston (1969) has reconsidered the complex of geographic variation, colonization, sympatry, divergence, and hybridization that typifies the *Passer domesticus* - *P. hispaniolensis* situation around the Mediterranean. Despite current interbreeding and obvious past hybridization, he concludes that full species status may be the simplest nomenclatorial solution for the *Passer* populations of the Italian peninsula. This is equivocal at best, but at least evidence indicates that selection has modified the hybrid populations away from the phenotypes available from a simple F-1 hybrid sample. This may be an example of a species of hybrid origin in animals, but it is not comparable in most features to the triploid salamander case.

It is important to note that the International Code of Zoological Nomenclature, in Article I, takes these facts into consideration and expressly forbids the giving of scientific names to "hybrids as such". It is equally important to note that the populational status of the hybrids is not an operative criterion in the wording of the Code. "Hybrids as such" frequently form populations, or "swarms". Examples for birds are cited above; Cory and Manion (1955), and works cited therein, document the well-known case in amphibians: *Bufo americanus* x *B. fowleri*.

Although valid plant species may rarely evolve from interspecies hybrids, no genuinely analogous phenomenon has ever been reported in the animal kingdom. Certainly, gynogenetic salamanders - being incapable of intrabreeding and requiring mating with a parental species for propagation - are not comparable to the few known examples in plants.

(2) *Are gynogenetic forms reproductively isolated?* As Uzzell (1964, p. 291) points out, the triploid *Ambystoma* females are genetically isolated from their parent species; that is, no recombination of genetic material takes place prior to embryogenesis. All gynogenetic specimens, however, require the presence (at least) of males of one or the other of the parental species; they are unable to reproduce by themselves. Thus, from a behavioral (and probably mechanical) viewpoint, these salamanders are reproductively bound to normal, diploid mates. Further, their genetic isolation is individual, not populational. That is, every triploid individual is genetically isolated from every other; each specimen would thus qualify as a reproductively isolated entity, in the simplistic, genetic sense.

(3) *Is gynogenesis analogous to parasitism?* If behavioral and mechanical factors bind triploids to diploids, and thus prevent the former from evolving independently, cannot the same be said of a strictly host-specific parasite? Waitz (1959, 1960), and works cited therein, provides examples of strongly host-specific parasites in amphibians. An analogy to gynogenetic salamanders is strained at best. Host-specific parasites are not close relatives of their hosts; certainly, they do not share their host's genome. They live within their host individuals just as non-parasitic organisms live within habitats of clearly defined limits. For a parasite, the host is the environment; for a triploid female salamander, the diploid male is simply the functional mate. True, the parasite needs its host species in order to survive, and the triploid salamander needs the diploids. However, a fish needs the water, and we all need the air. Environmental features and habitats are necessary for the survival and evolution of all species. Members of the opposite sex, required as mates, are not meaningful analogs of environmental features and habitats; parasites' hosts are.

(4) *Are gynogenetic and parthenogenetic forms different from a taxonomic viewpoint?* If parthenogenetic forms can evolve by means other than hybridization, then one barrier to the recognition of some of them as species is immediately overcome. It is true that parthenogens do not qualify for species status by intrabreeding; at least, however, they are sharply distinct from gynogens in not requiring behavioral (or mechanical) interbreeding with other species. If one adopts the excellent evolutionary species concept of Simpson (1961), then many parthenogens are at least closely analogous to biological or genetical species, and may usefully be regarded as such. Some parthenogens, like the lizard *Gymnophthalamus underwoodi* (see Thomas, 1965) are either not apparently of hybrid origin, or, like various *Cnemidophorus* (see Zweifel, 1965, Wright and Lowe, 1968, and works cited therein) have evolved in a unitary manner (just like other normal species) so far away from any mere interspecies hybrid that determining putative "parent species" is impossible with present evidence.

The situation with the gynogenetic salamanders is in sharp contrast: the form called "*platineum*" has a full, diploid genome from *A. jeffersonianum* and a single set of chromosomes from *A. laterale*. The form "*tremblayi*" is the converse: a full diploid genome from *A. laterale* plus a single set from *A. jeffersonianum*. The

triploid salamanders are phenotypically intermediate between their diploid parent species in direct proportion to the respective quantities of genetic material present. Thus, these gynogens are strictly "hybrids as such" and show no adaptively significant heritable characteristics of their own. They possess no independent ecological niche, a criterion of admitted importance even to Maslin (op. cit., p. 219). Thus, in the cases at hand, at least, a strong argument can be made for very separate taxonomic treatment of gynogens and parthenogens.

(5) Are gynogenetic individuals teratological specimens? The International Code of Zoological Nomenclature, in Article I, expressly forbids the giving of scientific names to "teratological specimens". In normal parlance, a "teratological specimen" is simply a freak, monster, or other abnormal production. All normal vertebrate animals are diploid; all valid species of the genus Ambystoma are bisexual diploids, including the two parental species of the triploids in question: A. laterale and A. jeffersonianum. None has a genome (or phenotype) that is merely a combination of some two other species. Therefore, triploid genomes, formed by simple combinations of the genomes of distinct species in the genus Ambystoma are abnormal formations. Organisms resulting from such a genome are teratological in simple English. Because a comparatively large number of parthenogenetic, naturally occurring forms exist, a strong case can be made that at least some of these are the result of normal formations, and thus not teratological. I do not know of any gynogenetically reproducing form not resulting from some "abnormal formation", and the phenomenon remains freakishly rare in nature.

In summary:

I. Valid species of hybrid origin, in plants, are characterized by: a. intrabreeding as the normal reproductive method. b. a lack of interbreeding with parental or other species. c. significant, adaptive, heritable differences from the parental species, not replicable by a simple combination of parental characteristics.

II. Valid parthenogenetic species are characterized by: a. reproductive independence from all other species. b. significant, adaptive, heritable characteristics not directly the result of hybridization between parental species. c. ecological evidence of independent, unitary evolutionary role, such as a distinctive niche.

III. The gynogenetic salamanders presently known are, from a genetic viewpoint, simple hybrids in the sense of the Code, and are also teratological specimens in the sense of the Code. They fail to qualify as species where some other forms of hybrid origin, or parthenogenetic forms, do qualify because: a. intrabreeding is impossible. b. interbreeding with parental, or other, species is their only method of reproduction. c. they possess no significant adaptive, heritable characteristics of their own, but merely combine characteristics of their parent species. d. they possess no distinctive evolutionary role or ecological niche.

An argument could be advanced that gynogenetic salamanders may be an incipient stage in a process leading to parthenogenesis and the establishment of evolutionary and ecological independence. This is certainly possible, and should it actually occur, a reappraisal of their status would be in order.

On the basis of present evidence, however, whatever we choose to regard them as -- teratological specimens of the species with which they are associated, or hybrids between jeffersonianum and laterale -- the triploids should not be regarded as separate species, either logically or legally. Thus, the name platineum Cope should be returned to the synonomy of A. jeffersonianum (Green), and tremblayi Comeau to the synonomy of A. laterale Hallowell.

UNREVIEWED-UNEDITED COMMUNICATIONS

Chromosomes of the hylid frog, Phyllomedusa dacnicolor Cope

Charles J. Cole

Among the 450 or so species of hylid frogs in the world is a group of approximately 40 Neotropical species in the subfamily Phyllomedusinae. Most authors agree that these frogs comprise a distinctive phylogenetic unit at the subfamilial level, but there is still considerable discussion as to their classification at the generic level. Duellman (1968, 1970) recognizes three genera: Agalychnis, Pachymedusa, and Phyllomedusa. He considers Pachymedusa monotypic, including only P. dacnicolor, and further suggests that this is a generalized species similar to the ancestral stock from which all the Recent forms evolved. Pyburn (1970) contested one of the important characteristics used by Duellman (1968) to define Pachymedusa, and agreed neither with Duellman's generic classification nor with his suggestion that P. dacnicolor is so primitive.

Inasmuch as earlier investigations indicated that phyllomedusines are distinctive among New World hylids in chromosome number (Duellman and Cole, 1965; Duellman, 1967) and at least one species is a tetraploid (Becak, Denaro, and Becak, 1970), the karyotype of Phyllomedusa dacnicolor is described in detail here with the hope that improved knowledge of the chromosome cytology of the phyllomedusines will result in improved systematics.

Chromosomes of 50 bone marrow cells at mitotic metaphase were examined on slides prepared by means of the colchicine, hypotonic citrate technique used by Cole, Lowe, and Wright (1968). Samples were examined from the following five specimens (four males, one female): No. 18350 in the herpetological collection at the University of Arizona, from Acapulco, Guerrero, Mexico; Nos. 84288-84290 in the amphibian collection at the American Museum of Natural History (AMNH), from the northern outskirts of Alamos, Sonora, Mexico; and AMNH No. 84291, from Quintera Mine, Sierra de Promontorios, ca. 9.0 mi. (by rd.) W. Alamos, Sonora, Mexico. I am grateful to Robert L. Bezy and Philip V. Colbert for assistance in the field, and to Richard G. Zweifel for criticizing the manuscript.

Phyllomedusa dacnicolor has a diploid number (2n) of 26 chromosomes; 14 (7 pairs) are larger macrochromosomes and 12 (6 pairs) are smaller (Fig. 1). Chromosomes 11 and 13 are the closest to being perfectly metacentric, chromosomes 3, 9, and 12 are subtelocentric, and the rest are submetacentric, with some variation in relative arm lengths (compare nos. 1 and 2). Chromosome number 6 has a wide heterochromatic band on the short arm near the centromere. No pair of heteromorphic chromosomes was found.

Phyllomedusines are the only New World hylids known to possess a haploid or basic number of 13 chromosomes (2n = 26), and all phyllomedusines for which such information is available have this number. Chromosome numbers are known for the following Mexican and Central American species: P. annae (n = 13), P. calcarifer (n = 13), P. callidryas (n = 13, 2n = 26), P. dacnicolor (n = 13, 2n = 26), P. helenae (n = 13, 2n = 26), and P. lemur (n = 13) (Duellman and Cole, 1965; Leon, 1970). The only other phyllomedusine for which the chromosome number is known is the South American Phyllomedusa burmeisteri, which is the only one whose karyotype has been published previously (Becak, Denaro, and Becak, 1970). This is a tetraploid species having 52 chromosomes, and thus polyploidy has occurred independently in at least two subfamilies of the hylidae (see also Wasserman, 1970). In the karyotype of P. burmeisteri it is clear that the basic chromosome number is x = 13, and the relative size and morphology of each of the pairs is very similar to those in P. dacnicolor. The most conspicuous differences are that in P. burmeisteri chromosome 8 is subtelocentric (submetacentric in dacnicolor), chromosome 11 is subtelocentric (metacentric in dacnicolor), and chromosome 7 appears to be relatively smaller. Unfortunately, the position of conspicuous heterochromatin in P. burmeisteri, if any, was not described.

The only other hylids known to have a haploid number of 13 chromosomes are several Australian and New Guinean species of the genera Litoria (Australo-Papuan Hyla of earlier authors; Tyler, 1971) and Nyctimystes (Duellman, 1967; Stephenson and Stephenson, 1970). Of these, karyotypes have been published for only two: Litoria caerulea and Litoria phyllochroa (Stephenson and Stephenson, 1970). The karyotypes of these two species are much alike and differ from the karyotype of Phyllomedusa dacnicolor. The most conspicuous differences occur in the positions of the centromeres on chromosomes 5, 8, 9, and 12, in the position of the conspicuous heterochromatin (near the tip of the long arm of chromosome 11 in the Australian forms), and in the size-group classification of the chromosomes. Thus the differences between the karyotypes of the Australian species of hylids with 2n = 26 chromosomes and the Mexican Phyllomedusa dacnicolor with 2n = 26 are greater than those between P. dacnicolor and the South American Phyllomedusa burmeisteri (excepting its polyploid condition!), although the differences between all of them are not very extensive.

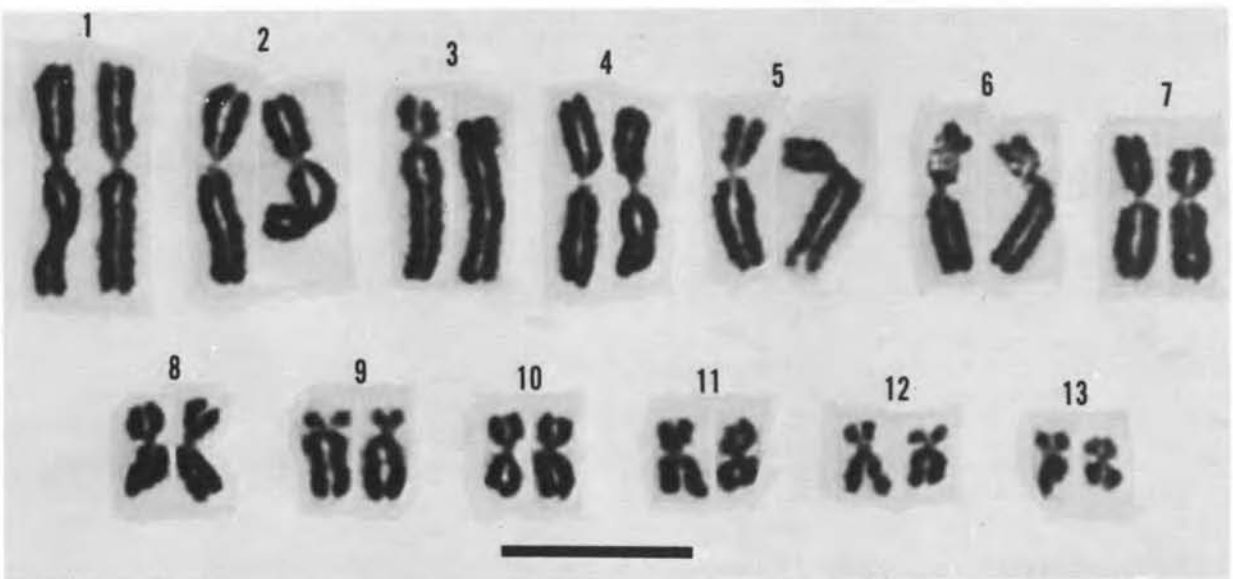

FIG. 1. Representation of the karyotype (2n = 26) of a male specimen of Phyllomedusa dacnicolor (AMNH 84289). The line represents 10 micra.

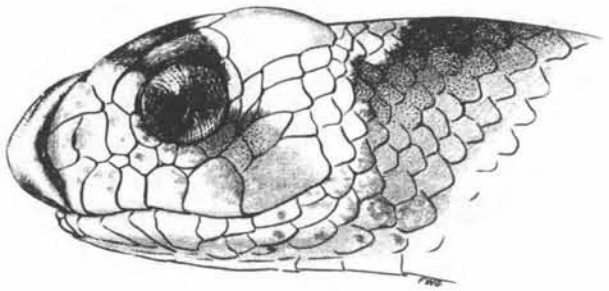
LOST MEMBERS

Mail addressed to the following persons has been returned, marked "ADDRESSEE UNKNOWN." We would appreciate current addresses.



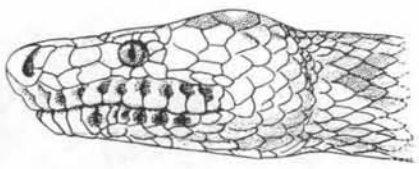
HOWARD LAWLER, Tennessee Herpetological Society, Belmont College, Nashville, Tenn. 37203.

BENGT FLOREN, Zetterslund, Funbo, Uppsala, Sweden.

DAVID J. MILLER, USASTRATCOM, APO San Francisco, Calif. 96343.

MEMBERS DESIDERATA

DONALD MERKLE (Biology Dept., Univ. of Dayton, Dayton, OH 45409) would like to secure individuals of all species of Clemmys, especially Clemmys (Sacalia) bealei. Specimens will be used in a systematical analysis utilizing comparative serum protein electrophoresis. Specimens will be returned, if desired.



Phyllorhyncus browni

TANZER MEMORIAL FUND

As most of you know, Ernest Tanzer died on January 23, 1971, of a malignant lymphoma after a prolonged stay at M.D. Anderson Hospital in Houston, Texas. Ernest's wife, Glenda, gave birth to their daughter prematurely last August also at M.D. Anderson.

If you wish to contribute to a Memorial Fund to be presented to Glenda to help in the payment of the many debts incurred by his illness, please contact Dr. Robert B. Chiasson, Dept. of Biological Science, University of Arizona, or Dr. Howard K. Gloyd, Dept. of Biological Sciences, University of Arizona, Tucson, Arizona. Please make checks payable to Mrs. Glenda Tanzer.

BOOK REVIEW

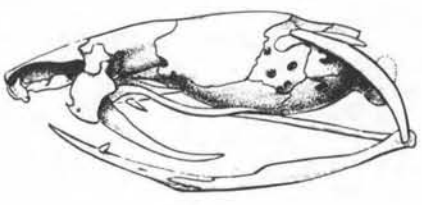
THE HYLID FROGS OF MIDDLE AMERICA. By William E. Duellman, illustrated by David M. Dennis. 1970. Monograph, Mus. Nat. Hist., Univ. Kansas (1): 2 vol., xii + 753 p., 72 pl., 234 text-fig. $25.

It is a relatively rare event in this era of "modern" biology, with its overweaning emphasis on the fallacies of the philosophy of scientific materialism, reductionism and mechanism as adequate bases for relating to nature, its attempt to force the unique features of living systems into the outmoded explanations of 19th century physics and its ignorance of the complexity and emergent quality of biologic problems that are not readily fitted into laboratory analysis nor easily abstracted by mathematical models, to receive a substantial work in systematic herpetology that can once again awaken us to wonder at the mystery and diversity of life. The appearance of Bill Duellman's, THE HYLID FROGS OF MIDDLE AMERICA, affords such an opportunity for the reader who dares look upon it with openness to his or her own feelings.

When I first received my copy, it was with a sense of excitement that I rapidly scanned its pages, and began, as a herpetologist who has worked in these parts of the world and with many of these same wondrous creatures, to note the high quality of the study, its completeness, attention to detail, broad scope, and most of all, the detailed drawings (hands and feet and skulls of almost all species, all known tadpoles and their mouth parts) and the superlative plates based on living animals (all species; 31 color plates, 100 species) prepared by Dave Dennis. At the same moment, I sensed the profound feeling of achievement that the author must have felt upon seeing this culmination of nearly twenty years of work, including ten intensive years of field and laboratory study and five years in final preparation for publication. His accomplishment has required a single-minded purpose, devotion to arduous and time-consuming fieldwork, to the dullness and drudgery of laboratory workup and to perserverance in the face of opportunities for new experiences in other climes, which in the final stages of completion are so tempting to any author surfeit with reading and checking the same old section for another time. What a vast relief to lay that burden down! What a pleasure to see the finished work, not just as you imagined it to begin with, not just the way you would like it to appear, but done complete, a finished product of your own creation. At that moment the work is yours and no other's. Let the book reviewers and critics see it as they may, later on! They can never dilute, even with their acid barbs, your feelings of the moment. And simultaneously emerged my own memories of nights and days along some of the same jungle trails, with the clouds and rainy winds on the ridges of the mountains, the distant calls of unknown frogs, the friends and companions in the search; where suddenly, always unexpectedly, you catch a glimpse of a new part of yourself darting through the trees in the dark woods, passing as a shadow across the moonlit path, splashing down the glittering stream, roaring out of a fiery volcano, cascading down a waterfall, flying above the canopy top in the green valley below or playing hide-and-seek with the light and shadows among the fallen leaves on the forest floor.

And wondering after that whether a scientific, critical, judgemental review of a work that can evoke such feelings and memories isn't really out of place. What is the meaning of such a review, anyway? To cut off the anxiety of facing the new book forthrightly and experiencing it as it is for you, I suppose. After all, when the critical intellect looks at anything carefully it vanishes, and if someone else (a reviewer) will do the job, then most of the joy (or pain) of discovery can be drained away before you buy and you can avoid the chance of being surprised, bored, amazed or stimulated by your own response to the work. In effect, the reviewer can make the book vanish before you purchase it, a remarkably silly waste of everyone's time and your money. "Ah! But doctor, we respect your opinion of the work and wish to honor it by following your evaluation of its value, construction, artistry, and deficiencies." My reply to that is, if you really respect my opinion, then reach out to the experience of encountering this book, without benefit of someone else's scholarly phrase and well-turned, sly but acceptable, hostile wit. Make the book yours, let your feelings and memories flow -- and then decide if you like the book -- don't ask me to do it for you!

And having said all this, I will add that this book can be read, like all works of human creativity at several levels at once. To those who wish it to be so, the study is a modern taxonomic revision of the tree-frogs of Middle America based upon the features of external adult morphology, tadpoles, cranial osteology, chromosome numbers, breeding calls and geographic distribution; with copious illustrations of all stages and characteristics and distribution maps. In this regard, it is the first modern attempt to deal with a large taxonomic (Hylidae) and geographic (Middle America) segment of the New World tropical frog fauna and stands as a bright counterpart to the similar works on tropical African and Asian frogs prepared in the last twenty years by a series of distinguished herpetologists. At another level, it provides a basis for the comparison of ecologic zonation and diversification among the tropical tree-frogs, a dominant tropical forest-adaptive type, in South America, Africa, Madagascar, Asia, and New Guinea. The data in Duellman's work will have broad interest and can probably be utilized by others interested in tropical species problems.



At still another level, the two volumes tell us much about the author, for although limited by the dry bone-yard conventions of scientific prose, this treatise like any creative work of art -- poetry, novel, essay or book review -- mirrors the inner world and imagination of its writer. And thus for those who can read the messages, Bill Duellman tells about his strengths, his weaknesses, his desires and aspirations, his hostilities and anxieties, his need for human warmth and appreciation, his need for acceptance, his pride of knowledge, his hope for immortality and his fear of death. All these things and more.

And at yet another level, what does this work contribute in the total context of biological knowledge? In tropical American herpetology, it is likely to remain an unassailable model for taxonomic works to come; a stimulus for different kinds of studies on these frogs than were possible prior to this work because of taxonomic chaos and ignorance of the opportunities provided by the diversity of adult, larval, ecologic and geographic patterns, now firmly elucidated. Perhaps it will also encourage herpetologists and ecologists elsewhere, interested in or living in the vast unexplored tropical world to new undertakings -- although the synthetic sections (pp. 654-693) that should provide such encouragement were not particularly stimulating for me, very probably because of my familiarity with the ideas and patterns discussed. But most likely very few others will take up the mundane approaches mentioned in the preface (p. vi.) of this work or follow these jungle trails to high adventure in search of golden frogs.

A hundred years from now, this monograph probably will have little significance to any but a few specialists studying the remnants of the world fauna. Its scientific appeals today are essentially only to those esoteric few who regularly peruse the HERPETOLOGICAL REVIEW. But even so, I can imagine in that not far-distant time, a young man or a young woman pulling down from the shelves in some dark archives, the dusty two volumes of this work, not checked out in forty years, and opening the yellowing pages to read the words and see the figures -- and at that moment being transfigured by emotion and stimulated to begin their own search for that experience that is life itself. And if these volumes do that for even one person, is it not enough?

MEETINGS AND SOCIETIES

CALENDAR 1971

15-19 June....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Los Angeles.

19-22 August....SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES, Annual Meeting, Univ. New Mexico, Albuquerque (cosponsored by the HERPETOLOGISTS' LEAGUE).

29 August - 4 September....AMERICAN INSTITUTE OF BIOLOGICAL SCIENCES, Annual Meeting, Colorado State Univ., Fort Collins.

28-29 December....HERPETOLOGISTS' LEAGUE, Annual Meeting, Philadelphia (with AAAS; cosponsored by the SSAR).

INDIVIDUALS AND INSTITUTIONS

The NEW YORK ZOOLOGICAL SOCIETY, in a recent news release, states that it "has been forced to close permanently its WILLIAM BEEBE TROPICAL RESEARCH STATION in Trinidad" for financial reasons. It is also reducing the support for its research division, the INSTITUTE FOR RESEARCH IN ANIMAL BEHAVIOR.

The TEXAS NATURAL HISTORY COLLECTION (U Texas) now includes some 38,000 herpetological specimens. For information, write:

Robert F. Martin, Curator of Zoology
Texas Memorial Museum
University of Texas
24th and Trinity
Austin, Texas 78705

JAMES R. DIXON (Texas A&M U), with five students, made a herpeto-ecological transect of the Sierra Madre Oriental of Mexico last summer. He and JAMES F. SCUDDAY (Sul Ross St. Coll) are also investigating the ecology of six species of Cnemidophorus in West Texas.

WILLIAM E. DUELLMAN and THOMAS H. FRITTS (U Kansas) visited Peru in search of Marsupial frogs (Gastrotheca) in January.

CARL GANS will move from SUNY-Buffalo to the University of Michigan as Professor and Chairman of the Department of Zoology.

C. OdC. DIEFENBACH will also move from Buffalo to Michigan.

HOBART F. LANDRETH (Secty-Treas, Herpetologists' League) will move from Southwestern State College (Oklahoma) to the University of Oklahoma as Associate Professor of Zoology (half-time) and Research Director of the Oklahoma City Zoo.

CARIBBEAN RESEARCH PAGE

In December, 1970, HOWARD W. CAMPBELL, THOMAS PATTON, and PETER C. H. PRITCHARD (Univ. Florida, Gainesville, Florida 32601) traveled to Jamaica at the request of the Jamaican Government to examine the status of their crocodile populations. A recent rape of these populations by a group of Americans caused some concern to Mr. Bernard Lewis of the Institute of Jamaica, and Mr. Keats Hall (Jamaican Forestry Department). They asked Tom Patton, well-known in the area through his paleontological activities, to gather a group to evaluate the impact of the slaughter. They also requested recommendations for future protective legislation, if needed, and immediately imposed an embargo on crocodiles and crocodile products being shipped from the country.

The group was well received in Jamaica, and the project was given radio and TV coverage. A Jamaican air force plane and pilot were placed at their disposal, and boats and guides were made available for night work in the marshes. In three days they overflew the southern, western, and northwestern portions of the island, and developed a fair estimate of the distribution and quality of available crocodile habitat. They also talked with many natives to form an impression of the areas of greatest crocodile densities, and to assess the local attitudes toward the animals. The overall impression was that Government officials and local citizens are tolerant-to-favorable in their attitude toward crocodiles, and that the chief problem lies with components of the society (native and tourist) that require exotic sport to occupy their free time.

The hunting of this species on Jamaica has been moderate until recently, and they concluded from night visits to the marshes that C. acutus still exists in low-to-moderate numbers throughout the available habitat. It is nowhere abundant, as far as they could determine during their short stay. The group feels that proper management instituted in the next year or two could be effective in restoring populations sizable enough to permit moderate sport hunting or commercial cropping within a decade or less. Current hunting practices should be halted, and they recommended a two-year study to establish an ecological baseline for development of a sustained yield management/conservation program. Subsequent discussions with Jamaican officials revealed that the Government would support such a study with satisfactory personnel and in-country facilities. Campbell, Patton, and Francis Rose are making plans to initiate the study. [26 Apr 71]

RONALD I. CROMBIE (National Zoological Park, Smithsonian Institution, Washington, D.C. 20009) is working on the taxonomy of Antillean hylid frogs, with current emphasis on Jamaican species. He spent six weeks in Jamaica during the summer of 1970, gathering data on Hyla cruciallis, and plans to extend ecological and behavioral studies to the other Jamaican Hyla. Crombie is also collecting data on the eggs and larvae of all Antillean hylids, Bufo, and Leptodactylus, and has started tracing the history of introductions both into, and from the Antilles. He has recently summarized the status of introduced populations of Hyla squirella in the Bahamas (QUART J FLORIDA ACAD SCI, in press). In collaboration with Albert Schwartz, he is working on Hispaniolan hylids, the St. Lucia Hyla, and Aristelliger. [26 Apr 71]

JUDY STAMPS (Dept. Zoology, Univ. California, Berkeley, CA 94720) has been working on Anolis aeneus behavior for the past several years, in Grenada and the Grenadines. She is interested in film analysis of displays and field analysis of social behavior. [27 Apr 71]

W. MICHAEL CAREY (Dept. Biology, Univ. South Florida, Tampa, FL 33620) is researching the ecology and behavior of West Indian rock iguanas (genus Cyclura). To date he has studied in the field C. macleayi caymanensis and C. m. lewisi on the Cayman Islands (4 weeks, 1965); C. pinquis on Anegada, British Virgin Islands (6 weeks, 1968); C. cornuta and C. ricordii on Hispaniola (1 week, 1968); and C. inornata and C. figginsi on the Exuma Cays, Bahamas (3 weeks, 1970). He plans to visit all Cyclura populations in the West Indies eventually for additional ethoecological studies, and has launched (with Albert Schwartz) a systematic review of the genus. [26 Apr 71]

HOWARD W. CAMPBELL (Dept. Zoology, Univ. Florida, Gainesville, FL 32601) is conducting a short-term study of the acoustic behavior of Aristelliger praesignis. Campbell and Richard Franz will visit Jamaica and the Cayman Islands during the coming summer to obtain recordings and observations of the vocal activity of this species and to collect live specimens for further laboratory studies of their social behavior and auditory physiology. [26 Apr 71]

HERNDON G. DOWLING (Dept. Herpetology, American Museum of Natural History, New York, NY 10024, and "Dowling House," Port Maria, Jamaica) is preparing a loose-leaf CATALOGUE OF JAMAICAN AMPHIBIANS AND REPTILES in a somewhat less technical format than that of the "American Catalogue." He would appreciate contributions from persons with specific interests in the Jamaican fauna. [30 Apr 71]

MEMBERSHIP IN THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles.

Regular dues are $8 for persons living in the United States and Canada, $6 for those in other countries.
Sustaining Members pay $10, and Contributing Members $15.
Institutional Subscription, $16.

Write: HENRI C. SEIBERT
Treasurer, SSAR
Department of Biology
Ohio University
Athens, Ohio 45701

MEMBERSHIP IN THE HERPETOLOGISTS' LEAGUE

All persons interested in herpetology are eligible for membership.

Dues are $8 for Regular Members, $10 for Fellows. Institutional Subscription, $15.

Write:
HOBART F. LANDRETH, Secty-Treas.
Herpetologists' League
Department of Biology
Southwestern State College
Weatherford, Okla. 73096

SUBSCRIPTION TO THE CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

A loose-leaf series of species accounts of the amphibians and reptiles of the Americas, with special emphasis on those in the United States and Canada.

The Binder, Index Tabs, and all 100 accounts published to 1970 cost $18.00 to individuals, $20.00 to institutions. Subscription to the 25 accounts to be published in 1971 is an additional $5 for individuals, $7 for institutions.

CHANGES OF ADDRESS

Please inform us of your address changes as soon as possible. Each returned copy of HERPETOLOGICAL REVIEW costs us (and you) about 25 cents more in postage and considerably more in handling.

Send address changes directly to:

HERPETOLOGICAL REVIEW
Genera of Reptiles Project
American Museum of Natural History
New York, N.Y. 10024

We will see that changes go to the mailing lists of SSAR, Herpetologists' League, and CATALOGUE, as well.

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be type-written on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $23.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/8 inches (one column) or 9 1/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 12 3/4 inches). Line cuts are reduced about 25 per cent in processing. [See also the special instructions for "Un-reviewed."]

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

UNREVIEWED-UNEDITED COMMUNICATIONS

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions. Drawings should be made to widths of 3 1/2" (one column), 7 1/4" (two columns), or 11" (three columns). Each vertical inch of drawing takes up six lines of text. The three-column format allows about 270 four- to five-word lines (35 characters and spaces) per page.

Page charges are: $20 for a single page; $40 for the two-page maximum. Include an allowance for the title and author's name and five lines for the address and received date. Send a check for the proper amount with the manuscript. Or, if you prefer, we will bill you that amount for reprints.

S S A R

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

The SSAR encourages the acquisition of knowledge on amphibians and reptiles, and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communications between amateur and professional workers.

Membership is open to anyone interested in amphibians and reptiles. Regular dues are $8, Foreign $6, Sustaining $10, Contributing $15, Life $150. Institutional subscriptions are $16. Address inquiries about subscriptions and membership to the Treasurer.

EDITORIAL

First, I must apologize for ruining those photographs in the last issue. Lack of coordination between Editor and Printer caused some of them to appear at postage-stamp size. With the issue far past its deadline, I did not have the time to make the changes.

Our mailing house has just come through with the figures for the last mailing of HERPETOLOGICAL REVIEW:

Domestic.....	1,653
Canada.....	54
Other Foreign	209
TOTAL	1,916

This is far different from the some 700 of a couple of years ago (there were about 300 as-yet-non-paying CATALOGUE subscribers included in this recent mailing). Such a number (which includes about 500 institutions) should certainly be able to carry the financial load of the publications and services of an outstanding herpetological society. -- HGD.

HERPETOLOGISTS' LEAGUE

The Herpetologists' League is an international organization established by Major Chapman Grant in 1936. It is dedicated to furthering knowledge of the biology of amphibians and reptiles.

In 1970 it had 940 members and fellows, 24 life members, 10 honorary members, and 400 institutional subscriptions to its journal, HERPETOLOGICA.

All persons interested in herpetology are eligible for membership. Dues are $8 for members, $10 for fellows. Institutional subscriptions to HERPETOLOGICA are $15.

Address the Secretary-Treasurer for information on membership and subscriptions.

HERPETOLOGY ON THE MAIN

Harry W. Greene

During the first four days of October, 1970, herpetologists from Austria, Brazil, Denmark, France, East and West Germany, Great Britain, Italy, Luxembourg, The Netherlands, Switzerland, and the United States met in Frankfurt am Main for the sixth annual convention of the Deutsche Gesellschaft fuer Herpetologie und Terrarienkunde ("German Society for Herpetology and Terrarium Keeping"). The wide variety of subject matter covered and the diverse backgrounds of the participants combined to make this a meeting of international interest.

Registration began on Thursday evening in the Frankfurt Zoo's Serengeti Room, and was followed by what is known in the States as a "smoker." At this time each participant received a meeting packet and a special herpetological issue of Natur und Museum. The remainder of the convention was held in the recently completed Festsaal of the Senckenberg Museum, and was formally opened on Friday morning by society president Dr. Konrad Klemmer. Formal papers were delivered during three morning paper sessions. During coffee breaks and recesses, members were able to view exhibits of herpetological books and reprints, live amphibians and reptiles, and terrarium supplies on the first floor of the museum.

Friday afternoon was devoted to tours. One group, led by Dr. Klemmer, took in the herpetological exhibits and the research section of the Senckenberg Museum. In addition to the fossil displays and preserved material (almost 100,000 specimens, including about 550 types and a complete collection of Recent crocodilian skulls), this included a look at the Museum's long-lived pair of tuataras -- the male has now been in captivity more than eight years, the female more than six. Meanwhile, another group under the direction of Dr. Dieter Backhaus and Dr. Christoph Scherpner explored the Frankfurt Zoo. Of special interest there is the "Exotarium" (of which Dr. Backhaus is Director), with its fine amphibians and reptiles -- Rana /Conraua/ goliath, six species of monitor lizards (including the bright green Varanus prasinus from New Guinea and a young Komodo dragon), a pair of Oriental pipe snakes (Cylindrofus rufus), the red and brown Calabar ground python (Calabaria reinhardtl), and both genera of Madagascan boas (Acrantophis and Sanzinia) -- to mention only the more unusual exhibits. Undaunted by the inconvenience of one of Frankfurt's frequent rain showers, Frau Inge Schroeder guided a third tour through the world-famous Palmengarten (200 gardeners!).

Friday evening was occupied by three outstanding film presentations, introduced by Dr. Backhaus. The first, by Dr. Erhard Thomas (Mainz), explored the prey catching and feeding behavior of a constrictor (Elaphe longissima). Next, Dr. Klemmer narrated "Observations on the vertebrates of the Algerian Sahara," by Claude Grenot (Paris), who was unable to attend. This included footage of desert birds and mammals, but emphasized thermoregulatory behavior by reptiles. The final film of the evening, By Dieter Krammig (Frankfurt am Main), depicted a herpetological collecting trip through Morocco.

A business meeting was held on Saturday afternoon, and the following officers were elected for two-year terms: President -- Konrad Klemmer, Vice Presidents -- Friedrich Golder (Mainz-Mombach) and Erhard Thomas, and Treasurer -- H. J. Mann (Neu-Isenberg). Heinz Schroeder (Senckenberg Museum) was elected to serve as Editor of SALAMANDRA for the next six years. A discussion of finances was followed by a vote to raise the dues to DM 25 per year (about $6.90). Rene Honegger proposed that the membership pass a resolution governing the conditions under which they would import or purchase certain endangered amphibians and reptiles. This was given a vote of general approval, and referred to a committee for further consideration. With the society's business attended to, the meeting was recessed to a local restaurant for an evening of good food and fellowship.

The convention enjoyed a record attendance of 183 persons, and was judged a great success by all with whom I talked. Much of the credit for this must surely go to President Klemmer and his two fine assistants -- Fraeulein Borchers and Frau Oelkers -- and the members of the Frankfurt "Group" of the society.

FIGURE 1. In 1815 Johann Wolfgang von Goethe, Germany's most famous poet, suggested to his fellow citizens that they establish a natural history society and museum. The SENCKENBERGISCHE NATURFORSCHENDE GESELLSCHAFT was founded two years later, named for Dr. Johann Christian Senckenberg, an eighteenth-century physician. During this same year (1817), Dr. B. J. Roemer-Buechner, a member of the Society, published the first account of the natural history of Frankfurt and its environs. In 1821 the first Senckenberg Museum building was erected, and the present structure (above) was completed in 1907.
Successive contributions of three particularly energetic naturalists -- Eduard Rueppell (1794-1884), Oskar Boettger (1844-1910), and Robert Mertens (now Director Emeritus) -- have made the museum's herpetological collection one of the finest in the world today.

Abstracts of Formal Papers

(Translated and adapted from German summaries prepared by Konrad Klemmer for Rundbrief #27, Deutsche Gesellschaft fuer Herpetologie und Terrarienkunde)

Boehme, Wolfgang (Kiel). STUDIES ON LIZARDS OF THE FAMILY LACERTIDAE.

A study of lacertid hemipenes, based on both live and preserved material, demonstrated that the epithelial spines appear only during the mating season. Their development could be induced at other times by hormone injection. Developing, mature, and regressing spines could be distinguished, but only mature cells were used for systematic study. No intraspecific variation was observed. Interspecific differences did not seem to have any functional significance, and were considered useful for systematic study.

Color slides of various genera and species of Lacertidae were shown in the second part of presentation, and the systematics of various groups discussed. Special attention was given the genera Lacerta and Eremias. It was suggested that certain lower categories, such as the subgenus Archaeolacerta, are unnatural groupings. Implications of hemipenis structure for the status of L. princeps, L. peloponnesiaca, L. laevis, and L. chlorogaster were given.

Studer, Peter (Basel). EXPERIENCES IN REARING KOMODO DRAGONS.

The Basel Zoological Garden received six young Komodo dragons from the Djokjakarta Zoo, one of which later died. The young lizards, which still showed the conspicuous juvenile pattern, were kept together so that their social behavior could be observed. They were maintained in a climatically controlled room and fed small mammals and birds. An infection of Salmonella was treated with repeated high doses of Chloramphenicol. Color slides and growth charts were used to demonstrate adaptation to captivity and satisfactory development.

Kaestle, Werner (Muenchen). OBSERVATIONS ON AUSTRALIAN ANGLE-HEADED AGAMIDS OF THE GENUS GONOCEPHALUS.

Gonocephalus boydi and G. spinipes were kept in a richly planted, three-meter-square indoor terrarium. Horizontal or sloping tree limbs were preferred as resting places. The animals did not bask and did not require high temperatures (18 degrees C at night, 25 degrees C during the day). They spent long periods of time sitting motionless. Food was not pursued, but simply grasped when it came within reach. From several clutches (each 3-6 eggs), one young lizard was hatched after an incubation period of three months.

Lanza, Benedetto (Florence). A NEW BLUE ISLAND RACE OF LACERTA SICULA FROM SOUTHERN ITALY.

A population of blue ruin lizards (Lacerta sicula) has been discovered on a small island off the Lucanian coast of Italy which resembles the well known blue lizards of Faraglione (near Capri). The type description of the new race will appear in SALAMANDRA. It is smaller than the Faraglione lizard (L. s. coerulea) and also differs from it in details of scalation and coloration.

FIGURE 2. Dr. Klemmer discusses the skeleton of Iguanodon, a Cretaceous dinosaur, with a group of visiting members in the First Inner Court of the Senckenberg Museum

---

Honegger, Rene (Zurich). THE PRESENT STATUS OF INTERNATIONAL EFFORTS TO CONSERVE ENDANGERED AMPHIBIANS AND REPTILES.

International cooperation will be necessary to intensify efforts to conserve amphibians and reptiles. The following steps have already been undertaken. In 1969 numerous sea turtle experts met at the offices of the International Union for Conservation of Nature and Natural Resources (IUCN) in Morges, Switzerland. The situation for all sea turtles is alarming, and consumers of sea turtle products have been informed of this on a worldwide basis. The New African Conservation Convention of September, 1969, ratified by numerous African countries, considered the establishment of new reservations, which would protect many amphibians and reptiles. The 1970 Endangered Species Act in the U. S. A. regulates the world-wide importation of endangered animals into that country, including amphibians and reptiles. The Tenth General Convention of the IUCN in New Delhi (1969) encouraged the governments of the Amazonian countries to restrict the export of their wildlife. National efforts to protect amphibians and reptiles must be strengthened. The buyers of these animals must be forced to cooperate and support efforts to conserve them.

Saint Girons, Hubert (Paris). ECOLOGICAL STUDIES ON CAMBODIAN SNAKES.

Observations gathered during travels in Cambodia were summarized. The habitats and adptations of various snakes were described and illustrated with color slides. Special emphasis was given to yearly cycles of reproduction, including maturation of ova and sperm, egg laying, and birth of young.

Mebs, Dietrich (Frankfurt am Main). WHY IS SNAKE VENOM POISONOUS?

Snake venom contains strong digestive enzymes and toxins. Toxins from Naja venom have been isolated several times in recent years, permitting clarification of their structures. An example is Cobrotoxin, from the venom of N. naja atra. It is composed of protein molecules, each consisting of 62 amino acids. These are arranged in unbranched chains, and a high proportion of basi amino acids is characteristic. The toxic nature of this venom reflects the sequence and arrangement of the different amino acids, and the spatial structure of the molecules. Like the arrow poison, curare, it acts on the end plates and halts the transmission of nerve impulses.

Clark, Richard J. (Molash, Kent, England, and Spetsai, Greece). THE SNAKES OF GREECE.

The zoogeography and regional distribution of Greek snakes was discussed. Morphological variation and comparative distribution of Coluber gemonensis and C. jugularis were described. Results of studies on the vipers of Greece (Vipera ammodytes, V. lebetina, and V. xanthina) were set forth, and their distribution reported. The Greek forms of Elaphe were discussed, and the specific status of E. rechingeri from the island of Amorgos considered.

Lanza, Benedetto (Florence). TRAVELS AS A NATURALIST IN EASTERN AFRICA.

Dr. Lanza's travels and observations in eastern Africa, especially in the Somali Republic, were illustrated with color slides. Of special interest were his photographs and comments on many rare or newly described reptiles.

Brodman, Peter (Ettingen). AMPHIBIANS OF THE BASEL REGION, AND STEPS FOR THEIR PROTECTION.

The amphibians fauna of the Basel region, including adjacent corners of Germany and France, is perhaps the richest of any comparable area in Western Europe. The author illustrated the various species and discussed their local distribution and habits. Suggested steps for conservation are as follows: protection of suitable breeding ponds, introduction of animals into appropriately constructed pools, cultivation of water plants, transfer of frog eggs, and protection of breeding migrations of frogs and toads from the dangers of highway traffic. For this last measure the author proposed drift fences to guide the animals through culverts under the roads. A special concern was the education of mankind, especially youth, about the biological significance of amphibians.

Hoogmoed, Marinus S. (Leiden). OBSERVATIONS ON THE FROGS AND LIZARDS OF SURINAM.

Dr. Hoogmoed discussed his observations on the distribution and ecology of the frogs and lizards of Surinam. His talk was supplemented with color slides and tape recordings of frog calls.

Stettler, Paul Heinrich (Ittigen/Bern). OBSERVATIONS ON CAPTIVE AMPHIBIANS AND REPTILES.

The speaker discussed and illustrated with color slides his observations on a number of rare or unusual amphibians and reptiles. Among others he mentioned, the treefrogs Hyla aurea and H. peronii and the appropriate terrarium for maintaining them in captivity; the unusual defensive behavior of Naultinus elegans, a New Zealand gecko; behavior and breeding of the agamid lizards Acanthosaura crucigera and Ceratophora tennentii; and the care and breeding of Erpeton tentaculatum, Acanthophis antarcticus, Atheris squamiger, Bitis caudalis, and Trimeresurus steinegeri.

Schultze-Westrum, Thomas (Assenhausen). AMPHIBIAN AND REPTILE HABITATS IN PAPUA.

Tropical amphibian and reptile habitats were discussed as they occur in New Guinea, including tropical rainforest, savanna, freshwater and brackish water swamps, and montane forests. Various amphibians and reptiles and their characteristic habitats were illustrated with color slides. Dr. Schultze-Westrum also discussed recent efforts to create a national park, and other protected areas in New Guinea were described. Problems associated with the introduction of Bufo marinus were mentioned, and possibilities for eradication or utilization (as "toad leather") of this species were suggested.

FIGURE 3. The internationally-known Frankfurt Zoo was first opened to the public in 1858. Shown here is a large lizard enclosure in the "Exotarium," a building housing marine invertebrates, fishes, amphibians, and reptiles.

CONSERVATION NOTES

AIMING AT ALLIGATORS ... The Louisiana Fish and Game Department is trying to crack the federal law protecting the endangered alligator so that it can sell $25 special hunting licenses to take alligators in the state. Could it be that $25 is not commercial when a state rather than an ordinary poacher collects it? (FROM MASS AUDUBON NEWSLETT)

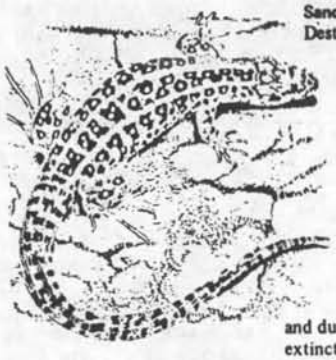
PAPUA & NEW GUINEA

CROCODILES. A person shall not purchase crocodile skins or crocodiles, dead or alive, or engage in the trade of crocodile shooting for profit without a licence. The licence shall specify the number to be taken and the area in which the trade is to take place. The size limits may be designated. No living crocodile can be exported without consent of the Director of Agriculture, Stock & Fisheries. /BIOL CONSERV 2(1): 50./

MEXICO

RIDLEY SEA TURTLES. Peter Pritchard evaluates the status of the various populations: Lepidochelys kempi nesting on the coast of Tamaulipas, "safe from extinction if existing protection schemes can be continued." L. olivacea (Atlantic population): "Safe if protection at Surinam nesting beach is continued."

L. olivacea (Eastern Pacific population): "suffering a probably dangerous level of exploitation." [BIOL CONSERV 2(1): 13.]



CUBA

CROCODILES. J. Groschaft (Inst. Parasitol., Czechoslovak. Acad. Sci., Prague) reports that both Crocodylus rhombifer and C. acutus are rare in nature, both on Cuba and the Isle of Pines. However, "numerous populations" of both species are bred in a special farm near Laguna del Tesoro (Zapata Peninsula, Las Villas Prov.).

AGAMA STELLIO. From an old photograph in the AMNH labelled, "Hugh S. Davis."

BRITISH ISLES

Sand Lizard in Danger
Destruction of its habitats on sandy heaths

and dunes is driving the sand lizard towards extinction in both Surrey and Lancashire, according to K. Corbett in the September *Oryx*. The larger of the two remaining Surrey localities, at Frensham, was recently destroyed by the Hambledon rural district council, in spite of a warning. In Lancashire the scheduling of another territory as a national nature reserve has not availed to avert a grave threat. The British Herpetological Society is now examining the position of the sand lizard in Britain as a matter of urgency, with a view to making recommendations for its conservation. (FROM ORYX)

RECENT PUBLICATIONS

RED DATA BOOK, Volume 3: Amphibia and Reptilia, compiled by Rene E. Honegger, 1970.

This volume is the first attempt to provide basic data on the status of rare and endangered amphibians and reptiles on a world-wide basis. Information is assembled in the form of short reports under a series of uniform headings. Adoption of a loose-leaf format allows any report to be replaced whenever new data warrants the publication of a more comprehensive or up-to-date sheet.

The volume may be obtained ($8.00) from:

The Director General
International Union for Conservation
of Nature and Natural Resources
1110 Morges, SWITZERLAND

SERPENTS DU LAOS, by J. Deuve, 1970. Bondy. 251 p., 32 pl., 18 fig., 3 maps. A systematic account of the 96 species that occur in Laos.

TEXTBOOK OF HERPETOLOGY, by C. J. & O. B. Goin, (Revised Edition) Freeman Co., 1971. We understand that this will be out on 15 March.

THE ZOOLOGICAL RECORD, Volume 105 (for 1968 literature). Amphibia ($6.00); Reptilia ($6.00).

EDWARD DRINKER COPE AND EVOLUTION

Robert W. Reese & Marcos Arellano-Armenta

In a previous publication (Smith and Reese, 1969) the junior author (Reese) reported the opportunity to examine many items, now the property of St. Marcos Arellano-Armenta, from the personal library of Alfredo Duges. Among them were two items of particular interest.

Duges' personal copy of Elementos de Zoologia (1884) is bound with interleaves, and they are completely annotated. In chapter 41 entitled "Trasformismo", a word which we are unable to translate literally, but probably meaning mutability of species or perhaps even evolution, he debates the acceptability of the theories of Lamarck and Darwin in the notations of the interleaves. In these he cites the opinions of a number of men involved in the controversy. Opposite page 226 is the notation, in Spanish, "3 The illustrious paleontologist (and) evolutionist E. D. Cope in a letter dated July 1886, tells me: I believe that positive proof of evolution cannot be found in paleontology nor in embryology, but in the study of the specific characters of the living beings". This is followed by the distinctive signature of Duges.

Among the papers is the original of the letter from Cope. Part of it is reproduced here (fig. 1), and a translation is offered below. That Cope appears lamarckian in his viewpoint is of interest.

Philadelphia 1/7 1886

Cher collegue et ami

J'ai reçu vos deux dernières lettres, et je dois vous donner mes excuses pour le retard de ma réponse.

J'ai déjà presenté a la Société Philosophique votre description du Rhinochilus nouveau, et j'ai laissé rester dans mes mains la description de la Stenostoma, selon votre demande.

A propos au sujet de l'évolution, je n'ai pas oublié votre objection a considérer

.....

Acceptez cher ami mes compliments et meilleures pensées. Votre E. D. Cope

Translation of letter from E. D. Cope to A. Duges

Philadelphia 1/7 1886

Dear Colleague and Friend:

I received your last two letters, and I must make my excuses for the lateness of my reply.

I have already presented to the Philosophical Society your description of the new Rhinochilus, and I have kept in my hands the description of the Stenostoma, according to your request.

On the subject of evolution; I have not forgotten your objection to considering as affirmative evidence the variations of species, among other examples, the species of Sceloporus. You wish to take the variations as hybrids. But this explanation is impossible, because the varieties or subspecies are not living ordinarily in the same country, nor with each other nor with their possible ancestors. Such a mixture of species, would be for that reason impossible even if the hybrids were fertile, which is not the case ordinarily as you know. In fact the intermediate forms are often inhabitants of regions widely separated, forming geographic types.

I really believe that the positive proof of evolution is not to be found in paleontology nor in embryology but in the study of the specific characters of living animals. Nevertheless, the previously mentioned sciences document very important contributing evidence. Also, I do not believe that Mr. Darwin has a complete theory of evolution, but I think that Lamarck has started on a much broader foundation, in spite of some idealisms mixed into his precise theories.

I thank you for the small box of reptiles. I am very happy to have your Hemidactylus navarrii? with the others.

Mr. Boulanger has recently published the second volume of the catalog of the lizards of the British Museum. It contains a large number of American species, and you will find it very important for your studies. This work is the best which we have, in spite of some awkwardness in the definitions of the genera.

Accept dear friend my compliments and best thoughts.

Yours,

E. D. Cope

next SSAR meeting

The Fourteenth Annual Meeting of the Society for the Study of Amphibians and Reptiles will be held at the University of New Mexico, Albuquerque, on 19-22 August 1971. The meeting will be co-sponsored by the Herpetologists' League.

The theme of the meeting will be THE ECOLOGY OF ARID-ADAPTED AMPHIBIANS AND REPTILES, with symposia and invited papers contributing to this subject.

Housing and meals will be available on campus, but such services are also found off-campus nearby.

Besides the prepared meetings, there will be a banquet, smoker, and field trips, with special activities planned for non-professional members and wives.

A CALL FOR PAPERS and an ABSTRACT form are enclosed on pages T-33 and T-34 of the CURRENT TITLES section of this issue.

These must be in the Editor's hands by 1 June, so that they may be printed in the pre-meeting, August issue of HERPETOLOGICAL REVIEW.

Additional information may be obtained from the Chairman of the Local Committee:

BOOK REVIEW

CONTROL OF GROWTH AND METAMORPHOSIS: Part II of ANIMAL HORMONES - A COMPARATIVE SURVEY. By Penelope M. Jenkin. 1970. Pergamon Press, Oxford, xviii + 383 p., 81 fig., 26 tab.

This volume, a continuation of part I: KINETIC AND METABOLIC HORMONES (1960), to which the reader is frequently referred, reviews the sources and actions of those hormones influencing growth, molting and metamorphosis in annellids, gastropods, cephalopods, several group of arthropods, and all classes of vertebrates. The text is well illustrated and indexed, with a list of references appearing at the end of each chapter.

It is a nice addition to a reading list for senior undergraduates in zoology and physiology. However, publishing houses like Pergamon would better serve the scientific community if they adopted the American Standard for Periodical Title Abbreviations: Z 39.5-1963 (American National Standards Institute, Inc., New York). This would eliminate inconsistencies in abbreviating the titles of journals.

BOOK REVIEW

LIVES OF SNAKES AND FROGS. By Hajime Fukada. 1970. Natural History in Pictures for Children. No. 10. Amphibians and Reptiles. Senshukai Co., Osaka, Japan.

This is a children's picture book of some common Japanese amphibians and reptiles. There are some pictures which may be used for identification of species and some depicting life history. Emphasis is on snakes and frogs, but some salamanders, turtles and lizards are also included. A separate commentary (in Japanese) explaining the pictures and containing additional photographs is provided. Also provided is a most welcome mimeographed English translation. Although in the translation there are numerous errors in spelling and some quaint phraseology, the meaning generally is clear.

The pictures by Izumi Tamai are especially appealing. They have a sketchiness, particularly in the backgrounds, that adds, rather than detracts, from their appeal. The animals look alive and, because of the subdued colors used, have a naturalness not often found in children's animal books.

I found this a delightful book and feel certain that it will introduce many children to amphibians and reptiles in a very pleasant way.

CURRENT HERPETOLOGICAL TITLES, XIV: 1970

Herpetological Information Search Systems
American Museum of Natural History
New York, N. Y. 10024

We have brought to your attention some 13,000 current titles in the pages of this journal to date.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts-Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses especially.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any current paper (e.g., 1970-1971) that is concerned with a member of a Recent order of amphibians or reptiles.

HERPETOLOGICAL REVIEW has appeared bimonthly, beginning in 1971. This means that the titles published here will be even more current. Further, the added issues will serve to reduce the titles-per-issue to a more manageable number.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This list contains titles of books and articles that have come to our attention during the period 1 January 1971 through 1 March 1971. Periodical title abbreviations follow the American Standard for Periodical Title Abbreviations Z 39.5-1963 (American National Standards Institute, Inc., New York).

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and L. Greene. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. Dr. Robert W. Winter provided us with translations of titles, abstracts and papers from Slavic languages. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

Members of the Herpetology Department and the Library staff of the Museum have continued to aid our efforts. No commercial computer service yet offers all of the facilities that we need and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 30 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

SYSTEMS

LATE NOTICE

HISS has just received word that its NSF grant has been cut by more than $40,000 (almost 40%) for the current year -- due to massive cuts in NSF funds for this division. We were warned that next year would not be any better.

We are not calling for donations or letters of appreciation, but we do hope that readers will subscribe to the new publications and services which we must initiate this year to help close the gap between production costs and monies available.

Notice of these new operations will appear in the next issue of HERPETOLOGICAL REVIEW

FOURTEENTH ANNUAL MEETING
SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
co-sponsored by
THE HERPETOLOGISTS' LEAGUE
University of New Mexico, Albuquerque
19-22 August 1971

C A L L F O R P A P E R S

The theme of the meeting will be THE ECOLOGY OF ARID-ADAPTED AMPHIBIANS AND REPTILES. However, papers on any herpetological subject are welcome. We would prefer that papers presented orally refer to work in progress or nearing completion. Presentation of results that have been published or that are in press usually are a waste of time for both author and audience.

Ordinarily we would expect an author to present no more than one paper, nor to request more than 15 minutes for its presentation. Exceptions will be considered, however.

An abstract of no more than 200 words must accompany this form to qualify for inclusion in the program (see other side). If an abstract is not received, the paper will be treated as a "title only" contribution.

PLEASE NOTE THE DEADLINE: 1 JUNE 1971.
(SEE OTHER SIDE FOR ADDRESS)

(PLEASE PRINT OR TYPE)

TITLE: _____

_____

AUTHOR(S): _____

_____

COMPLETE MAILING ADDRESS OF THE FIRST AUTHOR:

_____

_____

TIME REQUIRED: _____minutes.

EQUIPMENT NEEDED: 2x2" Slide Projector_____
16 mm Movie Projector_____

Other: _____

CATEGORY IN WHICH YOUR PAPER SHOULD BE PLACED: Anatomy ( ); Behavior ( ); General Ecology & Life History ( ); Genetics & Populations ( ); Physiology ( ); Techniques ( ); Systematics, Evolution, or Zoogeography ( ); Other ( ).

Is presentation of a paper a requirement for your attendance at the meeting? _____. If yes, does this mean that you will not receive funds or time for travel if your paper is not on the program? _____.

A B S T R A C T F O R M

Please type the final copy of your abstract in the form provided below. Use the format indicated in the sample: AUTHOR(S) in capitol letters; (institution) abbreviated in parens; and title. The allotted space is adequate for a 200-word abstract.

TILLEY, STEPHEN G. (Smith Coll.). Life history and population structure of Desmognathus ochrophaeus inhabiting wet rock faces.

Populations of the salamander Desmognathus ochrophaeus inhabiting wet, vertical rock faces in the vicinity of Mt. Mitchell, North Carolina were sampled and the information on size and age at maturity was compiled. Individuals were found to mature at smaller size at greater elevation and at a given elevation individuals were found to mature at smaller body sizes than they do in nearby woodland populations. Two population inhabiting rock faces at 5025 and 3590 feet above sea level yielded sample sizes sufficient to permit determination of age at maturity and juvenile growth rates from juvenile size-frequency distributions. In the higher elevation population sexual maturity is attained at larger body sizes, which in turn are attained by delaying the sexual maturity about one year relative to its occurrence in the lower population. The juvenile growth rates of the two populations are similar to one another and to those estimated for nearby woodland populations.

USE A CLEAN TYPEWRITER AND GOOD RIBBON. This copy will be offset directly for the published abstract.

An abstract is an abbreviated, accurate representation of a presentation. Make the abstract as informative as possible, so that readers may decide, quickly and accurately, whether they need to obtain additional information. Do not include information given in the title. State the purpose, methods, results, and conclusions, either in that order or with initial emphasis on findings (results and conclusions). Make sure that the taxa of the animals studied are indicated either in the title or the abstract.

Make the abstract self-contained, since it must be intelligible without further information. Be concise without being obscure; retain the basic information and tone of the presentation.

Write most abstracts in a single paragraph. Normally employ complete, connected sentences, active verbs, and the third person. Use nontextual material such as short tables and structural formulas only when no acceptable alternative exists. Employ standard nomenclature, or define unfamiliar terms, abbreviations, and symbols the first time they occur in the abstract.

CHROMOSOMES OF THE RHINOPHRYNID FROG, RHINOPHRYNUS DORSALIS DUMERIL AND BIBRON

Charles J. Cole

Rhinophrynus dorsalis is the only Recent representative of the American family Rhinophrynidae. Some of its morphological characteristics appear to be primitive and others appear derived. Consequently, the relationships of the Rhinophrynidae to other families of frogs are obscure (Hecht, 1963). The karyotype of Rhinophrynus dorsalis is presented here with the hope that these data may be useful sooner or later in determining its relationships.

Chromosomes of 31 bone marrow cells at mitotic metaphase were examined on slides prepared by means of the colchicine, hypotonic citrate technique used by Cole, Lowe, and Wright (1968). The four frogs (two of each sex) from which chromosomes were examined were collected by James Bockowski and Manuel Rubio in the Isthmus of Tehuantepec, along Highway 190 between Tehuantepec and Juchitan, Oaxaca, Mexico, on 3 August 1970. The specimens are in the amphibian collection of the American Museum of Natural History (AMNH 84256-84259). I am grateful to the collectors for contributing the live frogs for this investigation, to Philip V. Colbert for assistance in the field, and to Richard G. Zweifel for criticizing the manuscript.

Rhinophrynus dorsalis has a diploid number of 22 chromosomes: 14 (seven pairs) are large and eight (four pairs) are distinctly smaller (Fig. 1). Of the larger chromosomes, number 7 is metacentric, numbers 1, 2, and 5 are metacentric to submetacentric, and numbers 3, 4, and 6 are conspicuously submetacentric. Chromosomes 3, 4, 5, and 6 are rather similar in length, and thus, excepting number 5 which has a distinctive shape, they are often difficult or impossible to distinguish from one another. Of the four pairs of smaller chromosomes (none of which is small enough to qualify as a microchromosome), numbers 8, 9, and 11 are submetacentric, whereas number 10 is subtelocentric (nearly telocentric). In most cells, each of the pairs of smaller chromosomes is individually recognizable. Number 11, clearly the smallest, is also distinguished from the other small submetacentrics by virtue of its relatively shorter short arm. Number 10 is the only pair of subtelocentrics. Although numbers 8 and 9 are similar in size and shape, one of them (designated as no. 8 here) has a distinctive, consistent secondary constriction in the long arm near the centromere (Fig. 1). No pair of chromosomes is heteromorphic. The karyotype presented here is consistent with the chromosome number for Rhinophrynus dorsalis (n = 11) recently reported by Leon (1970).

Most students of anuran phylogeny agree that the following four Recent families are the most primitive: Ascaphidae, Discoglossidae, Pipidae, and Rhinophrynidae. Also, various authors consider that rhinophrynids have their greatest affinities with the pipids, although the relationship is not considered to be very close. It is of interest now, therefore, to compare the chromosomes of Rhinophrynus with those of representatives of these other presumably primitive families.

ASCAPHIDAE.-- Karyotypes of two species have been described and illustrated: Ascaphus truei ($2n$ = 42 or 44; Wickbom, 1950a; Morescalchi, 1967) and Leiopelma hochstetteri ($2n$ = 34 or 23; Morescalchi, 1968a). In neither Ascaphus nor Leiopelma do the karyotypic data suggest affinities with Rhinophrynus.

DISCOGLOSSIDAE.-- Karyotypes have been described and illustrated for Alytes obstetricans ($2n$ = 36 or 38) and Discoglossus pictus ($2n$ = 28) (Wickbom, 1949; Morescalchi, 1966). Also, chromosomes have been examined in three of the four species of Bombina ($2n$ = 24; Wickbom, 1949; Makino, 1951; Morescalchi, 1965, 1966). The chromosome morphology of Rhinophrynus is most similar to that of Bombina and Discoglossus, although the resemblance is not particularly close, and there is a difference in chromosome number.

PIPIDAE.-- Chromosomes of two African species have been examined: Xenopus laevis ($2n$ = 36; Wickbom, 1949; Mikamo and Witschi, 1966) and Hymenochirus boettgeri ($2n$ = 24; Morescalchi, 1968b). Two American species have been examined also: Pipa parva ($2n$ = 30 telocentric chromosomes; Morescalchi, 1968b) and Pipa pipa ($2n$ = 22; Wickbom, 1950b). Only in the case of Pipa pipa, among the pipids, is the karyotype similar to that of Rhinophrynus dorsalis. Not only do these two species have the same number of chromosomes ($2n$ = 22), but P. pipa also has chromosomes of similar sizes. The biggest reported differences in the chromosomes of these two species are in a number of centromere positions; Wickbom (1950b) reported that the seven smallest pairs of P. pipa are telocentric. These differences, however, may not be so large as they presently appear, because Wickbom did not have modern equipment and techniques available for his work. He did not use colchicine, for example, which provides clear recognition of centromere positions, and

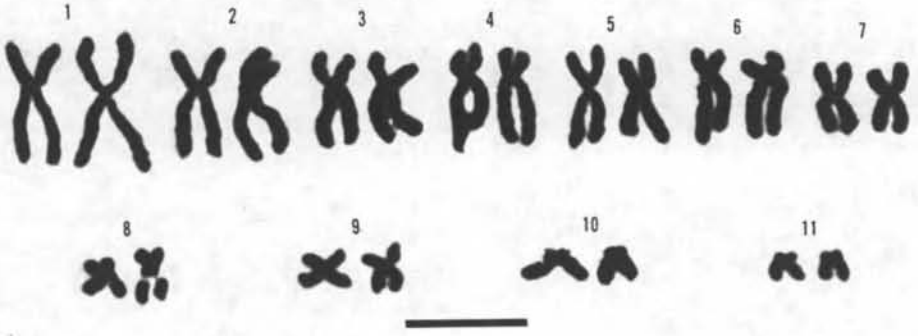

Fig. 1. Representation of the karyotype ($2n$ = 22) of a female specimen of Rhinophrynus dorsalis (AMNH 84256).

consequently his indications of centromere positions were sometimes inaccurate; this was most frequent with smaller chromosomes. Thus, the karyotypes of Pipa pipa and Rhinophrynus dorsalis might be extremely similar. It is, therefore, of considerable interest to obtain new preparations of the chromosomes of P. pipa, as well as of other pipids.

OTHER FROGS.-- Considering all other species of frogs that have been karyotyped and for which closely comparable illustrations are available, the species having karyotypes including 2n = 22 chromosomes (or x = 11 in polyploids) that strongly resemble those of Rhinophrynus are all members of the Leptodactylidae. The similarities in many cases include a secondary constriction on chromosome number 8, with conspicuous differences only in some details of centromere positions. The following leptodactylids have similar karyotypes: Leptodactylus bufonius, L. melanonotus, L. ocellatus, L. pentadactylus, Macrogenioglottus alipioi, Odontophrynus americanus, O. carvalhoi, O. cultripes, O. occidentalis, Physalaemus cuvieri, P. fuscomaculatus, P. pustulosus [reported as Engystomops pustulosus], and eight species of Pleurodema (Barrio and de Chieri, 1970; Becak, Becak, and Rabello, 1966, 1967; Becak, Becak, and Vizotto, 1970; Becak, Denaro, and Becak, 1970; Becak, Becak, and de Langlada, 1968; Bianchi and Molina, 1967; Bogart, 1967; Morescalchi and Gargiulo, 1969).

Other species of anurans that have the same chromosome number as Rhinophrynus dorsalis (2n = 22) do not also have such similar chromosome morphology, and thus they are not considered further here.

Thus, the karyotype of Rhinophrynus dorsalis, considered with reference to the karyotype data available for other anurans, does not necessarily validate placing the Rhinophrynidae among the most primitive frogs. A more definitive statement awaits the study of additional American pipids by modern methods.

UNREVIEWED-UNEDITED COMMUNICATIONS

AGONISTIC BEHAVIOR IN SOME CAPTIVE FROGS (RANA) FROM NEVADA

Frederick H. Emmerson & Fenton R. Kay

Brode (1959), Blair (1963), Durham and Bennett (1963), Emlen (1968), Schroeder (1968), and Weiwandt (1969) have observed combat in Rana clamitans and Rana catesbeiana associated with territories of calling males. Test (1954) observed agonistic behavior associated with feeding in Phylobates trinitatus. He noted that subadults and adults, predominantly females, aggressively defended their streamside feeding stations. Brattstrom and Yarnell (1968) reported territorial defense in Leptodactylus melanotus that increased when food was introduced into the experimental terraria. We observed agonistic interactions during feeding of captive Rana sp. (near pretiosa) from Duckwater, Nye County, Nevada.

Two groups of nine frogs were initially placed in ten-gallon glass terraria, containing a moist sand terrestrial substrate and water to a depth of one inch. The frogs were later transferred to two 30 x 30 in. areas in a galvanized metal container, 9 in. deep. Each partition contained sand, wheat seedlings, and a shallow enamel pan, 12 x 8 in., set flush with the soil surface. The frogs were maintained on a diet of mealworms (Tenebrio sp. larvae), wingless fruit flies (Drosophila melanogaster) and occasional cockroaches (Periplaneta americana).

Upon presentation of food (mealworms distributed on the sand or in petri dishes) the frogs attacked one another, biting, butting, and pouncing squarely upon one another. Even in the presence of excess food, aggression persisted to the extent that the frogs often did not feed. Preoccupation with combative behavior was such that many mealworms crawled off and ceased to be available as food. Occasionally a pair of frogs would grapple for possession of a single mealworm, with the food alternating between animals several times before being consumed. On several occasions frogs attacked the single tiger salamander (Ambystoma tigrinum) housed for a time with one of the groups. These attacks occurred as the salamander moved from place to place as the frogs fed.

Ritualized sequences of behavior were not seen, but on a few occasions one frog postured to another in a manner similar to the "challenge" posture figured by Weiwandt (1969) or the "attention" posture figures by Brattstrom and Yarnell (1968). On only one occasion was the second frog observed to assume what appeared to be a submissive posture. The usual end to a display was active biting and kicking by one frog or the other.

The larger frog of any sparring pair was not necessarily the initiator of aggressive behavior, nor did it always succeed in driving away the smaller animal. There was no observable difference in aggressive proclivities between male and female or mature and immature frogs. No dominance relationships were evident at any time.

Over a period of months, frogs were removed from each group. Agonistic behavior remained prevalent in the face of diminishing group size. A single adult pair was kept for several months in a 15-gallon terrarium and was fed on a flat rock. Combat continued to occur, but not with every feeding.

Hediger (1950) has classified animals as continuous or occasional feeders. Rana in nature would fall into the continuous category. In effect, these captive frogs were forced by the conditions of captivity, to become occasional feeders. Although the temptation existed to structure a study in which the frogs' agonistic behavior could be quantified, we felt that the resulting data would say little, if anything, about the life style of the animals in nature. Moreover, behavior in captivity is subject to change by manipulation of variables. We found, for example, that presentation of a different prey item elicited a different style of feeding activity. When cockroaches, and to a lesser extent fruit flies, were presented, the frogs hopped about in pursuit of these active, climbing insects, in contrast to gathering around a dish of relatively inactive mealworms. No combat was observed as the frogs fed on cockroaches, and very little when they were fed fruit flies.

We thank Dr. James E. Deacon for providing laboratory facilities during this study, and Dr. Ralph J. Raitt and Steven J. Bissell for reviewing the manuscript.

REGIONAL SOCIETIES PAGE

Since the publication of the list of Herpetological Societies, Amateur & Professional (HERPETOL REV 2(3): 6-9), a committee of SSAR has been formed for liaison with regional Herpetological societies. Members of this committee (John S. Applegarth, Arden Brame, J. T. Collins, James R. Dixon and I. Gilboa, Chairman)have already established contact with many of the societies in order to formulate a program of services and activities. Here is a supplementary list of new societies:

Bi-State (NY and NJ) T. and T. Soc. (William Galluccio, 96-35 Corona Ave., Corona, NY 11368).

Iowa Herpetological Society (Henry Wallace, 147 Tonawanda Dr., Des Moines, IA 50312).

Kentucky Herpetological Society (Eddie Ashmore, Box #2, 2825 Lexington Rd., Louisville, KY 40206).

Nevada Herpetological Society (Bill Cobb, Jr., 4909 Eugene Ave., Las Vegas, NV 89108 or Lendre Embree, 6229 Factor, Las Vegas, NV).

New Mexico Herpetological Society (John S. Applegarth, Dept. of Biol., Albuquerque, NM 87106). Membership dues $1.00 per year. A well-spent dollar for their informative NEWSLETTER.

Pacific Northwest Herp. Soc. (Ernie Wagner, Woodland Park Zoo, 5400 Phinney Ave., Seattle, WA 98107). Regular membership dues $5.00, students or subscribers $2.00 per year. They publish a Bulletin irregularly.

West End Reptile Association (St. George's Church, 300 West D St., Ontario, CA 91761).

CALIFORNIA TURTLE & TORTOISE CLUB
P.O. Box 90573, Los Angeles, CA 90045

WESTCHESTER CHAPTER: Meets on the 4th Friday of every month at the Alondra Park Headquarters Bldg., 3850 Manhattan Beach Bl., Lawndale, CA. Time: 7:30 to 10:00 PM (opens at 7:00 PM).

FOOTHILL CHAPTER: Meets on the 1st Friday of every month at the Glendale Federal (Community Room), 2350 Honolulu Ave., Montrose, CA.

MEMBERSHIP: $5.00 yearly, individual; $10.00 yearly family (2 or more). These include subscription to the TORTUGA GAZETTE; subscription only, $4.00 per year.

SOUTHWESTERN HERPETOLOGISTS SOCIETY

The Southwestern Herpetologists Society was founded in 1954 in Orange County, Calif. An early purpose was to encourage and inspire young herpetologists. Twelve years later, in September 1966, the San Gabriel Valley Branch of the Society was formed. In June 1967, the San Fernando Valley Herpetological Society voted to become the San Fernando Valley Branch of the Southwestern Herpetologists Society. These three branches comprise the present structure of the Society. The Constitution and Bylaws of the Society were printed in the March 1970 issue of HERPETOLOGY, the Society's quarterly publication. The Society is an unincorporated association, although an effort is being made to have it approved as a nonprofit corporation.

ORANGE COUNTY BRANCH: Meets on the 4th Wednesday of every month (except Dec.) at the Isaac Walton League Bldg., 1714 Santa Clara, Santa Ana, at 7:30 PM. Secretary-Treasurer: Randy Limburg, 318 E. Redwood, Orange 92667; phone (714) 637-4906.

SAN GABRIEL VALLEY BRANCH: Meets on the 2nd Wednesday of every month at the Eaton Canyon Nature Center, 1750 N. Altadena Dr., Pasadena, at 7:45 PM. Visitors most welcome. Secretary-Treasurer: Don Griffith, P.O. Box 2054-D, Pasadena 91105. Phone (213) 794-1866 (Nature Center).

SAN FERNANDO VALLEY BRANCH: Meets on the 3rd Monday of every month at the Reseda Recreation Center Bldg. (2nd fl.), 18411 Victory Blvd., Reseda, at 7:30PM. Secretary-Treasurer: Betty Reynolds, 2890 Rock St., Simi 93065, phone (805) 526-0918.

MEMBERSHIP: Unlimited member, $5.00; family member, $3.00 (for additional members in same household); commercial member, $5.00, plus 10% of sales at meetings; subscribing member, $3.00.

RAY PAWLEY is the recently elected president of the Chicago Herpetological Society.

A special double issue of HERP (Bull. New York Herpetol. Soc.) 6(3-4) is dedicated to the American ALLIGATOR. Issued in 1971, it includes reprints of papers by R. L. Ditmars and K. P. Schmidt.

UNREVIEWED-UNEDITED COMMUNICATIONS

PERENNIAL COMMUNAL NESTING IN THE BLACK RACER (COLUBER CONSTRICTOR)

George W. Foley

Communal nesting behavior has been reported for only four species of North American snakes. Blanchard (1930, 1936) records nests of the eastern ringneck snake (Diadophis punctatus edwardsi) containing eggs deposited by a number of individuals. Presence of shell fragments in some nests indicated use of the same sites for at least three consecutive seasons. Instances of communal nesting for the smooth green snake (Opheodrys vernalis) are noted by Stille (1954), Cook (1964), and Fowler (1966). Lynch (1966) records a group of 76 eggs of the pilot black snake (Elaphe o. obsoleta), plus shells from the previous year; other shell fragments, possibly from two years before, were found nearby. Evidence of communal nesting in the eastern fox snake (Elaphe vulpina gloydi) is presented by Patch (1919, p. 60), who notes "apparently, several individuals sometimes place their eggs in the same site, as on one occasion three specimens and half a bushel of eggs were found under a section of log." A somewhat similar experience with the same species is recorded in the field notes of Dr. and Mrs. Max Hecht (pers. comm.). Approximately 150 eggs, estimated by Dr. Hecht to represent eight clutches, were found within a single log.

On July 13, 1963, I found three nesting sites of the northern black racer (Coluber c. constrictor) near Sterling Furnace, Orange County, New York. The sites, located upon an old concrete foundation several feet in height, were partially obscured by grasses and other low plants growing in the soil and cinders mixture that formed a broad platform at the edge of a wooded tract. Eggs had been deposited beneath pieces of plywood lying fifteen to twenty feet apart. Two groups of eggs were barely sheltered by separate pieces of wood approximately 2 feet square; the third and largest group was concealed beneath a 4 x 3 foot section partially covered with earth. One site contained 22 eggs and more than 12 shells from the year before. The second contained more than 20 eggs and a similar number of year-old shells. The third site contained about fifty eggs and somewhat more than 50 shells from the previous season. The first and third sites were photographed on July 17 by Richard G. Zweifel (Figs. 1, 2).

The first group of 22 eggs was collected and incubated by means of the plastic bag technique (Zweifel, 1961); all hatched on August 16. Twenty-one hatchlings were released at the nesting area in early September. All eggs left in situ had hatched, but a careful search of the surrounding area at the time produced no hatchlings. On a subsequent visit on May 30, 1965, I found ten or twelve shells of 1964 vintage under the larger shelter. The other two shelters had rotted away during the intervening months.

Fitch (1963) records an average of 16.8 eggs per clutch for the northern racer based on 14 sets of 7 to 31 eggs each. Therefore, the two individual groups of about 20 eggs may have represented single clutches, but the larger complement resulted from the efforts of at least two and possibly three females. Thus, these observations document the use by Coluber c. constrictor of the same nesting sites for minimum periods of two and three years respectively, and show communal nesting at one site for two years.

IMPORTANT NOTICE
Camp's "Classification of the Lizards"

Because of the extended postal service shutdown in England this past winter, the reprinting of Camp's lizard book will be delayed slightly due to the interruption of communication between the editor and Dr. Garth Underwood, who has written the introduction. It is anticipated that subscribers' copies will be mailed during summer 1971.

The Society regrets this inconvenience.

K. Adler, Editor
Facsimile Reprints in Herpetology

MEETINGS AND SOCIETIES

CALENDAR 1971

12-16 April....FEDERATION OF AMERICAN SOCIETIES FOR EXPERIMENTAL BIOLOGY, Annual Meeting, Chicago.

15-17 April....ASSOCIATION OF SOUTHEASTERN BIOLOGISTS, Annual Meeting, Richmond, Virginia.

23-25 April....SYMPOSIUM ON, "The world of reptiles," University of California, Berkeley (see p. 40).

23-24 April....SOUTHWESTERN ASSOCIATION OF NATURALISTS, Annual Meeting, Fayetteville, Arkansas.

1-2 May....JOSHUA TREE TURTLE RACES, Joshua Tree, Calif.

23 May....7th ANNUAL CALIFORNIA TURTLE & TORTOISE CLUB SHOW, Pasadena.

15-19 June....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Los Angeles.

19-22 August....SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES, Annual Meeting, Univ. New Mexico, Albuquerque (cosponsored by the HERPETOLOGISTS' LEAGUE). /See pp. 36, T-33./

29 August - 4 September....AMERICAN INSTITUTE OF BIOLOGICAL SCIENCES, Annual Meeting, Colorado State Univ., Fort Collins.

28-29 December....HERPETOLOGISTS' LEAGUE, Annual Meeting, Philadelphia (with AAAS; cosponsored by the SSAR).

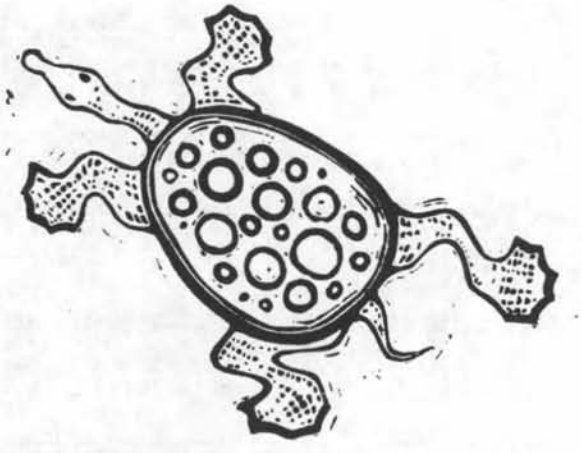
INDIVIDUALS AND INSTITUTIONS

NEWARK MUSEUM OF NATURAL HISTORY. "The collection of tailless amphibians was increased by a gift of Australian frogs by Daniel C. Wilhoft, a gift of frogs of the southern United States by Douglas Rossman, and a number of California specimens obtained from Anthony J. Gaudin. The salamander collection was augmented by a selection of salamander life history material donated by James D. Anderson.

"An excellent collection of snakes from the New Jersey Pine Barrens was received from Robert Brandner." [MUS N S (NEWARK) 1969: 55]

DAVID B. WAKE (Mus. Vert. Zool., U. Cal.) was elected Chairman of the ASZ's Division of Vertebrate Morphology. Among his students, ex-students and collaborators, are RON LAWSON with whom he co-authored a monograph on the vertebral column of Eurycea bislineata, RICHARD WASSERSUG, who is studying the feeding mechanisms of anuran larvae, JAMES L. EDWARDS who is studying the evolution of the neck region in salamanders, and RICHARD WORTHINGTON, who is working on a morphometric analysis of regional variation in salamanders. R. ERIC LOMBARD recently completed his doctoral work on an evolutionary analysis of the auditory and vestibular elements of the inner ear of salamanders.

MEMBERS DESIDERATA



JOSEPH T. COLLINS (Mus. Nat. Hist., Univ. Kansas, Lawrence, Kansas 66044) would like to obtain a set of Holbrook's "North American Herpetology" (either first or second edition). He will trade Daudin's eight-volume "Reptiles" and Guenther's "Reptiles of British India," plus other selected volumes.

THOMAS G. ZACCONE (Dept. Zoology, Univ. Rhode Island, Kingston, R.I. 02881) would like to obtain living specimens of Heterodon platyrhinos, H. nasicus, H. simus, Farancia abacura, F. erytrogramma, and Pseudoeryx plicatilis for karyotyping. Locality data would be appreciated.

RECENT DEATHS

ERNEST C. TANZER (Bryan, Texas) died of cancer, 23 January 1971.

JOHN ALLEN RAHNIS (Maryland Herpetol Soc.) died as a result of an automobile accident, 19 January 1971.

CHANGES OF ADDRESS

HISS now provides mailing lists for the CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES and the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES. With this issue, the HERPETOLOGISTS' LEAGUE mailing list has also been added to our computerized file.

PLEASE SEND CHANGES OF ADDRESS for any of these activities directly to us, we will inform the appropriate officers.

HERPETOLOGICAL INFORMATION SEARCH SYSTEMS
Department ML
American Museum of Natural History
Central Park West at 79th St.
New York, N.Y. 10024

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be typewritten on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $16.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/8 inches (one column) or 9 1/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 12 5/8 inches). Line cuts are reduced 25 per cent in processing.

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

****

UNREVIEWED-UNEDITED COMMUNICATIONS

****

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

****

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions (see Advice to Authors).

Page charges are: $20 for a single page (148 lines of about 40 characters and spaces); $40 for the two-page maximum (300 lines). Include an allowance for the title and author's name and five lines for the address and received date. Send a check for the proper amount with the manuscript, or if you prefer, we will bill you that amount for reprints.

S S A R

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

The SSAR encourages the acquisition of knowledge on amphibians and reptiles, and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communications between amateur and professional workers.

Membership is open to anyone interested in amphibians and reptiles. Regular dues are $8, Foreign $6, Sustaining $10, Contributing $15, Life $150. Institutional subscriptions are $16. Address inquiries about subscriptions and membership to the Treasurer.

EDITORIAL

****

With this issue of HR we welcome an additional 650 members and subscribers of the HERPETOLOGISTS' LEAGUE (those who are not also members of SSAR). As indicated on this page and elsewhere, the cosponsorship of HR was one of the steps taken by the societies at the December meetings in Chicago.

It has been our hope that HR would become truly a newsletter for all people interested in amphibians and reptiles, rather than just the organ of a single society. The action in Chicago has brought HR a giant step toward this goal.

Another act of the SSAR Board provides an additional step in this direction. It voted to allow individuals who are not members of either society to subscribe separately to HERPETOLOGICAL REVIEW. Therefore, this number is being mailed to some 300 subscribers of the CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES that are not HL or SSAR members -- just to show them what they have been missing. We are hopeful too that the new possibility of separate subscription will allow HR to expand its circulation in the regional and specialized societies. We hope also to gain subscribers among the many ecologists, embryologists, physiologists, parasitologists, and others who work with reptiles and amphibians, but who do not consider themselves herpetologists. At least "Current Titles" should be of interest to all. If the "fringe groups" provide news items, etc., as well, the gain will be mutual.

Three new Departments are introduced in this issue. A "Geographic Distribution Page" is intended for new information on amphibian and reptile distribution, and the correction of erroneous information. A "Caribbean Research Page" will provide information on current research projects and other herpetological activities in this very active region. Perhaps of most importance on a long-term basis is the initiation of a "Regional Society Page," intended to provide a place for recording the activities of some of the smaller herpetological associations. We are hopeful that members who are interested in these various aspects of the field will find time to contribute to these new sections.

Other departments are under consideration and some (e.g., karyotype records) are under development now. The broader base of our new readership should provide even greater opportunity for development. Your suggestions and aid will be greatly appreciated. -- HGD.

****

HERPETOLOGISTS' LEAGUE

The Herpetologists' League is an international organization established by Major Chapman Grant in 1936. It is dedicated to furthering knowledge of the biology of amphibians and reptiles.

In 1970 it had 940 members and fellows, 24 life members, 10 honorary members, and 400 institutional subscriptions to its journal, HERPETOLOGICA.

All persons interested in herpetology are eligible for membership. Dues are $8 for members, $10 for fellows. Institutional subscriptions to HERPETOLOGICA are $15.

Address the Secretary-Treasurer for information on membership and subscriptions.

Mississippi State Univ.
State College, Miss. 39762

To the Members of the Herpetologists' League and SSAR:

You may have noticed that the current issue of Herpetological Review bears a statement on the masthead of joint sponsorship for its publication. In December, 1970, at separate meetings, and later by committees in joint session, the governing boards of the two organizations approved an exploratory program to identify areas and activities in which interaction might bring about improvement in the several services offered to the herpetological community. In addition to joint sponsorship of the Herpetological Review for 1971, reciprocal invitations to co-host the Albuquerque meeting of SSAR, August 19-22, and the Philadelphia meeting of H L, during the week, December 26-31, will be made.

To examine the implications of long range interaction, and the possibility of a joint meeting for 1972, the governing boards established a committee consisting of three members from each organization. Full reports of the committee's recommendations will be made to the membership of the two societies in August and again in December. The East and West locations of the two meetings strongly increases the possibility that a significant number of members of the two societies will attend at least one of the two meetings, and thus be on hand to discuss the Committee report.

In the meantime, both of us would appreciate any comments you might care to offer concerning the above action and suggestions for specific ways and means of implementing cooperative action designed to strengthen the communicative aspects of herpetology, both oral and published.

Robert E. Gordon
Chairman, SSAR
University of Notre Dame

Wilmer W. Tanner
President, H L
Brigham Young University

Besides the President of HL and the Chairman of SSAR, who serve ex officio, the following were appointed to the committee mentioned above:

Representing the SSAR

KRAIG ADLER
Department of Biology
University of Notre Dame
Notre Dame, Ind. 46556

HERNDON G. DOWLING
Department of Herpetology
American Museum of Natural History
New York, N.Y. 10024

HENRI C. SEIBERT
Department of Zoology
Ohio University
Athens, Ohio 45701

Representing the HL

HOBART F. LANDRETH
Department of Biology
Southwestern State College
Weatherford, Okla. 73096

CLARENCE J. McCOY
Carnegie Museum
4400 Forbes Avenue
Pittsburgh, Penn. 15213

VICTOR H. HUTCHISON, Chairman
Department of Zoology
University of Oklahoma
Norman, Okla. 73069

As indicated, V. H. Hutchison was elected Chairman of the committee at its first meeting.

SSAR'S KANSAS CITY MEETING

One hundred and sixty-five persons, from 31 states and 8 nations, attended the Society's Thirteenth Annual Meeting 27-30 August 1970 at the University of Missouri - Kansas City. The meeting was dedicated to guest of honor Edward H. Taylor in recognition of his major contributions to herpetology. Society Chairman Ronald A. Brandon opened the meeting by introducing our hosts: Richard Armitage, UMKC Provost and Dean of Faculties; Wesley J. Dale, Dean of the School of Graduate Studies; Henry A. Mitchell, Associate Dean of the College of Arts and Sciences; and Harold C. Burdick, Acting Chairman of the Department of Biology. Provost Armitage welcomed the Society to the campus.

The highlight of the meeting was the symposium on "Evolutionary Biology of Anurans," organized by James L. Vial, Kraig Adler and William E. Duellman. It was supported financially by UMKC and presided over by W. Frank Blair. The consistently excellent presentations, containing some of the most significant papers on the subject in recent years, were followed by energetic discussions. A symposium volume edited by Dr. Vial, will be published by the University of Missouri Press.

Twenty-four additional papers were presented during sessions presided over by William W. Milstead, Roy W. McDiarmid and M. J. Fouquette. Abstracts of these papers follow this report.

The Board of Directors met Friday evening in a long and significant session. Several committees were authorized to make recommendations to the Board regarding: 1) selection of future meeting sites, 2) financial planning, 3) liaison with regional herpetological societies, 4) liaison with national herpetological societies, 5) SSAR history and membership campaign brochure, and 6) Society publications. Other important action included: 1) selection of the University of New Mexico, Albuquerque, for the August 1971 14th Annual Meeting; 2) increasing of dues for regular members from $6.00 to $8.00, for sustaining members from $8.00 to $10.00, for foreign members from $5.00 to $6.00, and for institutional subscriptions from $10.00 to $16.00; 3) to increase Herpetological Review from 4 to 6 issues a year; 4) decision to publish abstracts of papers given at our annual meetings in Herpetological Review; 5) a policy to distribute a list of SSAR members and their addresses to all members of the Society. Other items of business were referred to appropriate committees for preparation of recommendations to a mid-year meeting of the Board which was held in Chicago during the December 1970 meetings of AAAS.

At the Business Meeting on Saturday morning, a resolution prepared by the Committee on Conservation (N. Bayard Green, Chairman, M. Graham Netting, and Glenn Gentry) was read and approved:

"RESOLUTION -- Whereas the Society for the Study of Amphibians and Reptiles, concerned with the future of the North American fauna, views the introduction, intended or unintended, of foreign reptiles and amphibians into the continent, and especially the United States and its possessions, as a threat to our native species, and also views with concern any effort to introduce our native species into other parts of the world.

"Be it resolvad that the Society for the Study of Amphibians and Reptiles urges the United States Fish and Wildlife Service, and the various state departments of fish and game, to desist from introduction into the United States and its possessions of exotic wildlife, and to concern themselves with the betterment of our native wildlife and the saving of its habitats; and

"Be it further resolved that the Society for the Study of Amphibians and Reptiles deplores the lack of emphasis on the potential long-term adverse evolutionary consequences of the introduction of exotic species that has marked past introductions and present attempts at introduction of game and pet species, some of which represent taxonomic groups not compmising a part of our native fauna; and

"Be it further resolved that the Society for the Study of Amphibians and Reptiles supports the effective control of the importation of amphibians and reptiles by the United States government and its agencies, and the enactment of appropriate legislation regulating responsible and proper confinement and security of imported species."

Robert E. Gordon, Chairman of the Resolutions Committee, presented the following motion which was approved:

"The Resolutions Committee moves that the Society express its appreciation to:

1) Dr. Jamas Vial and his colleagues, William Milstead, Thomas Berger, Donald Smith, James Stewart, Cathy Ewert, Cathy Hunt, Roger Jensen, Linda Folkman and Paul Anderson, all members of the local committee, for their dedication and effort that insured the great success of the 13th annual meeting.
2) The University of Missouri - Kansas City for provision of the excellent facilities and helpful services in support of scholarly activity on the biology of amphibians and reptiles.
3) The Symposium participants for their stimulating and enthusiastic contributions on the state of our knowledge of anuran evolution. We look forward to the publication of this survey of contemporary anuran biology."

The Banquet and Social were held Saturday evening at the Roundtable Restaurant.

Presentation of the guest of honor award to Edward H. Taylor (right) by SSAR Chairman Ronald A. Brandon (left) and Meeting Chairman James L. Vial.

MEETING PROGRAM

THURSDAY, AUGUST 27. AM.

REGISTRATION: University Student Center (Main Lobby).

CALL TO ORDER: Ronald A. Brandon (S. Illinois Univ.), Chairman of the Society.

Welcome: Richard Armitage, Provost and Dean of Faculties, UMKC.

Introduction of Sponsors:

Wesley J. Dale, Dean, School of Graduate Studies, UMKC.

Henry A. Mitchell, Associate Dean, College of Arts and Sciences, UMKC. Harold C. Burdick, Acting Chairman, Department of Biology, UMKC.

SYMPOSIUM:
EVOLUTIONARY BIOLOGY OF ANURANS.

W. Frank Blair (University of Texas), Presiding.

SESSION I. THURSDAY. PM.

Introduction: Major Problems in Anuran Evolution. W. Frank Blair (Univ. Texas).

Origin and Early Evolution of Anurans. Richard Estes (Boston Univ.) and Osvaldo Reig (Univ. Central Venezuela) (Presented by Estes).

Bones, Frogs and Evolution: A Phylogenetic Dilemma. Linda Trueb (Univ. Kansas).

Transition from Archaic to Advanced Frogs. John D. Lynch (Univ. Nebraska).

Biochemical Techniques and Problems in Anuran Evolution. Sheldon I. Guttman (Miami Univ. Ohio).

Panel Discussion: Joseph A. Tihen (Univ. Notre Dame), Moderator. R. Estes, O. Reig, L. Trueb, J. Lynch, and S. Guttman; Discussants.

SYMPOSIUM. SESSION II.
FRIDAY, AUGUST 28. AM.

Evolution of Mating Behavior. George B. Rabb (Chicago Zool. Park).

Evolution of Reproductive Adaptations. Stanley N. Salthe (Brooklyn Coll., New York) and William E. Duellman (Univ. of Kansas) (Presented by Salthe).

Evolutionary Patterns in Larval Morphology. Priscilla Starrett (Univ. S. California).

Ecological and Behavioral Adaptations of Anuran Larvae. Richard Wassersug (Univ. California Berkeley).

Panel Discussion: Robert F. Inger (Field Museum of Natural History), Moderator. G. Rabb, S. Salthe, W. Duellman, P. Starrett and R. Wassersug; Discussants.

Participants in SSAR Symposium on "Evolutionary Biology of Anurans." ROW 1 (seated left to right): Arne Schiotz, Sheldon I. Guttman, Priscilla Starrett, W. Frank Blair, Linda Treub, Stanley N. Salthe, James P. Bogart. ROW 2: Jay M. Savage, John D. Lynch, George B. Rabb, Ian Straughn, Dean E. Metter, Richard Estes, Robert F. Inger, Richard Wassersug, David J. Merrell, William E. Duellman, Osvaldo Reig. Not shown: Joseph A. Tihen.

SYMPOSIUM. SESSION III. FRIDAY. PM.

The Geographic Distribution of Frogs: Patterns and Predictions. Jay M. Savage (Univ. S. California).

Evolution of Karyotypes. James P. Bogart (Univ. Texas).

Evolution of Mating Calls: Bioacoustical Considerations. Ian Straughn (Univ. Coll. Townsville, Queensland, Australia).

Evolution of Mating Calls: Ecological Considerations. Arne Schiotz (Danmarks Akvarium, Charlottenlund, Denmark).

Ecological Genetics of Anurans. David J. Merrell (Univ. Minnesota).

Panel Discussion: Dean E. Metter (Univ. Missouri-Columbia), Moderator. J. Savage, J. Bogart, I. Straughn, A. Schiotz and D. Merrell; Discussants. Concluding Remarks: W. Frank Blair.

FRIDAY EVENING.

BOARD OF DIRECTORS MEETING: University Student Center (Alumni Lounge).

CONTRIBUTED PAPERS
SESSION I. SATURDAY, AUGUST 29. AM.

William W. Milstead (UMKC), Presiding.

Further studies on serological relationships among colubrid snakes. Sherman A. Minton and Sylvia K. Salanitro (Indiana Univ. Med. Center) (Presented by Minton).

Two more toxic salamanders: Ambystoma maculatum and Cryptobranchus alleganiensis. Edmund D. Brodie, Jr. (Clemson Univ.).

Comments on boid (Serpentes) relationships. Herndon G. Dowling (Amer. Mus. Natur. Hist.).

Aggressive behavior among Costa Rican anoline lizards. Anthony A. Echelle, Alice F. Echelle (Univ. Oklahoma) and Henry S. Fitch (Univ. Kansas) (Presented by Echelle).

Effect of cyclic injections of melatonin on the biological clock of larval Ambystoma tigrinum. Douglas H. Taylor (Univ. Notre Dame).

Natural hybridization between Bachia intermedia and Bachia barbouri (Sauria: Teiidae). James R. Dixon (Texas A & M Univ.).

Comparative studies on activity patterns of Desmognathus quadramaculatus and Leurognathus marmorata. James L. Vial and James R. Stewart (UMKC) (Presented by Stewart).

Physiological comparisons of desert and montane populations of Ambystoma tigrinum. Jeff Delson and Walter G. Whitford (New Mexico State Univ.) (Presented by Delson).

CONTRIBUTED PAPERS
SESSION II. SATURDAY. PM.

Roy W. McDiarmid (Univ. S. Florida), Presiding.

Geographic variation of Ameiva undulata (Sauria: Teiidae.) Arthur C. Echternacht (Boston Univ.).

A serum protein study of Ozark Cryptobranchus. Edward Wortham and Max A. Nickerson) Arkansas State Univ.) (Presented by Wortham).

Toward a quantification of the ecological niche. Wm. W. Milstead (UMKC).

A comparative study of the body movements of displaying males of the lizard genus Sceloporus (Iguanidae). James R. Purdue (Univ. Oklahoma).

Squamation in caecilians. Edward H. Taylor (Univ. Kansas).

A new species of Batrachoseps (Slender Salamander) from the desert of Southern California. Arden H. Brame, Jr. (Eaton Canyon Nature Center).

Display behavior of Sceloporus horridus. Louis J. Bussjaeger (Univ. Oklahoma).

Development of tadpoles of Hyla gratiosa and Hyla femoralis. Ronald Altig (Mississippi State Univ.).

Special Illustrated Presentation: The Ozarkian Wildlife Region. Leland Payton (Sedalia, Missouri).

CONTRIBUTED PAPERS
SESSION III. SUNDAY, AUGUST 30. AM.

M. J. Fouquette (Arizona State Univ.), Presiding.

The ecology and distribution of Eurycea longicauda melanopleura and Eurycea lucifuga in western Missouri. H. Patrick Woolley (East Central Junior Coll. Missouri).

The formation of tadpole holes. Jeffrey H. Black (Univ. Oklahoma).

Seasonal movements and home range of Desmognathus fuscus throughout an annual cycle. Ray E. Ashton, Jr. (Miami Univ. Ohio).

Hybridization experiments involving Ambystoma dumerilii. Ronald A. Brandon (South Illinois Univ.).

Concerning the taeniata group of the genus Tantilla (Serpentes: Colubridae). Alan H. Savitzky and Hobart M. Smith (Univ. Colorado) (Presented by Savitzky).

The comparative courtship behavior of Chrysemys concinna suwanniensis and Chrysemys scripta elegans. John D. Davis (Mississippi State Coll. Women) and Crawford G. Jackson, Jr. (San Diego State Coll.) (Presented by Davis).

Analysis of discontinuous variation in the Central American snake Scolecophis atrocinctus (Colubridae). Stephen R. Edwards (Univ. Kansas).

Noteworthy records of reptiles and amphibians from the southeastern United States. Bruce Means (Florida State Univ.).

ALTIG, RONALD (Miss. State U.). Development of tadpoles of Hyla gratiosa and Hyla femoralis.

Development of laboratory-reared tadpoles of Hyla gratiosa and Hyla femoralis from Okaloosa County, Florida was followed from gastrulation until rear limb buds appeared. Emphasis was placed on color pattern development. The larva and premetamorphic tadpole of H. gratiosa has a unique striped and banded pattern that develops at about the time the eye appears, and this pattern is distinct from that of the prometamorphic tadpole. The prometamorphic tadpole undergoes considerable diel color change. The striped pattern typical of H. femoralis tadpoles does not fully develop until some time after the operculum closes. At first the tail musculature is bicolored. Later the lateral and dorsolateral light tail stripes are delimited, and the light dorsolateral body stripe is obliterated.

These patterns are probably important in camouflage. H. gratiosa tadpoles undergo an ontogenetic behavioral change.

****

ASHTON, RAY E. JR. (Miami U.). Seasonal movements and home range of Desmognathus fuscus throughout an annual cycle.

Thirty-five Dusky salamanders were tagged with Cobalt-60 (35-50 microcuries) and their movements monitored with a survey meter and scintillation probe. Distances moved, temperature of air, water, and substrata were taken each time the animal was located.

Average home range was calculated to be 1.67 meters squared with the largest area being 3.6 meters squared. The longest movement in one week was 10.2 meters, in twenty-four hours, 1.5 meters.

Winter movement was centered around underground spring and seepage areas where the temperature never dropped below 3°C. Average depth of these areas was about 30 cm. As many as fifteen adult Desmognathus fuscus were found in a 20 cm. squared area of one such retreat. These areas were composed of gravel and small pieces of limestone around which there was a constant flow of water. All salamanders found in this area seemed quite active.

****

BEZY, ROBERT L. (Los Angeles County Mus. Nat. Hist.). Systematic problems in the family Xantusiidae (Sauria).

Highly disjunct local populations with varying degrees of morphologic divergence make difficult the task of defining evolutionarily meaningful (or even morphologically consistent) species units in the family Xantusiidae. Selective pressures for saxicolous adaptations have led to morphologic convergence at the subspecies, species, and near-generic levels. Data on karyotypic variation, when considered together with morphologic, biogeographic, and ecologic information aids in the solution of generic and species problems in this small but puzzling family.

****

BLACK, JEFFREY H. (U. Oklahoma). The formation of tadpole holes.

Tadpole holes are circular depressions formed in soft layers of silt and fine sand in the bottom of shallow ponds. These are interesting features to geologists as they may be buried, fossilized, and preserved in the fossil record. Their formation has been attributed to interference ripple-marks, gregarious fish and tadpoles.

During the past 3 years in Oklahoma, over 30 temporary pools and the tadpoles inhabiting them have been observed. Tadpole holes were not present until May, 1970, during which time their formation was observed in a pool basin newly formed by road construction, 15.5 miles east of Norman, Cleveland County, Oklahoma. Numerous circular depressions with a diameter of 23 to 57 mm and a depth of 5 to 15 mm were regularly spaced over nearly the whole bottom of the pool. These circular depressions were made by the feeding activities of Bufo americanus charlesmithi and Pseudacris streckeri tadpoles. Depressions were further developed by aquatic beetles, snails and fairy shrimp.

BLAIR, W. FRANK (U. Texas). Major Problems in Anuran Evolution.

Two main themes are discussed. One addresses the accuracy of presently existing schemes for classifying the Anura, especially the higher categories, and the accuracy of our presently existing knowledge of the evolutionary history of the anuran taxa. The second theme concerns the suitability of anurans as material for elucidating evolutionary principles and mechanisms.

The multidisciplinary approach is stressed. Anurans are very well suited for the study of karyotypes, genetic compatibility, behavioral isolating mechanisms including those of mating call difference and response, and biochemical differences in such things as skin secretions and blood proteins. Added to the conventional characters of external morphology, osteology and myology, the sum of all of these attributes gives confidence in the conclusions that can be drawn.

Several examples of the utility of the modern methods in improving anuran classification are cited, as are potential sources of error if too few kinds of information are used.

Examples from Bufo are used to illustrate the utility of the multidisciplinary approach in establishing best estimates of the area of origin and history of spread of a particular taxon.

Possible utility of anurans toward a better understanding of the meaning of latitudinal gradients in species diversity and of the mechanisms of speciation of tropical animals are discussed.

****

BOGART, JAMES P. (U. Texas). Evolution of Karyotypes in Anurans.

Recent advances in methodology combined with an increased sampling of species enables us to come to a better understanding of the evolution of karyotypes in the Anura. Chromosome numbers in themselves are not sufficient information. Some species with the same chromosome number may be distantly related while other species in the same genus may have varying numbers. Several types of chromosal mutation may be demonstrated in the Anura.

Knowledge of karyotypic variation in some groups is helpful in understanding the evolution of the various genera and species. Karyotypic examination of large numbers of species and genera often reveals interesting patterns and relationship. The family Hylidae may be taken for an example. Chromosome numbers vary in this family from 18 to 52 (2n). Most of the karyotypes may be derived from a basic leptodactylid karyotype which has 26 chromosomes. In the genus Hyla, there are three major chromosomal groupings which would indicate very distant relationships for these groups. Other groups of species which have been given generic status are chromosomally very similar to species of Hyla and possibly do not warrant generic distinctness. It is often possible to group species on the basis of karyotypic similarity.

****

BRAME, ARDEN H. JR. (Eaton Canyon Nature Center). A new species of Batrachoseps (Slender Salamander) from the desert of Southern California.

The surprising discovery was made in the late summer of 1969, of a population of Batrachoseps living in a tributary of Deep Canyon, south and above the town of Palm Desert, at an elevation of 2500 ft., Santa Rosa Mtns., Riverside Co., California. This record represents the eastern-most locality and most arid environment for a salamander in California. The protected canyon has a continuous water seepage along the west facing cliff-like slopes that trickles above and below the limestone sheeting. The Batrachoseps seek shelter beneath the limestone during the hot dry months and migrate out to the canyon floor in the wetter winter months. Due to the less than an acre size of the locality and its uniqueness, it is urged that this Batrachoseps be placed on the rare and endangered list. The distinguishing characters of the Desert Slender Salamander are low numbers of trunk vertebrae (19-20); very large heads; long legs; large feet; reduced phalangeal formula of 0-2-3-2 for both hands and feet; and distinctive blackish maroon ground color spotted with silver and brassy iridophores dorsally and venter of tail flesh colored. The Desert Slender Salamander is one of the relict primitive forms in the genus. Its closest relative is Batrachoseps stebbinsi, the Tehachapi Slender Salamander.

****

BRANDON, RONALD A. (So. Illinois U.). Hybridization experiments involving Ambystoma dumerilii.

Reproductive compatibility between Ambystoma dumerilii, the Lake Patzcuaro achoque, and other species of ambystomatid salamanders is being tested under laboratory conditions. These data, and others related to reproduction, add to the understanding of relationships among Mexican ambystomatids.

Some results obtained thus far are: (1) There is a high potential for interbreeding between A. dumerilii and A. mexicanum, the Xochimilco axolotl; reciprocal crosses through both artificial insemination and spontaneous interspecific courtship yield offspring with no increase in embryonic deformity or larval mortality. (2) No reduction in embryonic or larval viability occurs in crosses between A. dumerilii and Michoacan A. amblycephalum (?) and Illinois A. tigrinum. (3) Some embryonic deformity and prehatching mortality appear in crosses between A. dumerilii and South Carolina A. talpoideum. (4) A small number of hybrid A. dumerilii female x Rhyacosiredon rivularis male developed normally. Larvae from all crosses are being raised for eventual tests of interhybrid and backcross fertility.

****

BRODIE, EDMUND D. JR. (Clemson U.). Two more toxic salamanders: Ambystoma maculatum and Cryptobranchus alleganiensis.

Injections of skin secretion from Ambystoma maculatum and Cryptobranchus alleganiensis into white mice proved lethal. Secretion was collected from enlarged glands concentrated along the tail ridge and parotoid region of A. maculatum; gland distribution is like that found in A. gracile and A. rosaceum. Defense posturing places these regions in proximity to the stimulus. The secretion of A. maculatum causes a drying, burning sensation to the tongue.

The skin secretion from C. alleganiensis was collected generally from the dorsal surface. This secretion is very bitter and causes a drying sensation to the tongue but does not burn.

Although lethal when injected, skin of these two salamanders was not toxic when injested by white mice and chickens. Skin secretions are nevertheless probably effective in repelling would-be predators.

****

BUSSJAEGER, LOUIS J. (U. Oklahoma). Display behavior of Sceloporus horridus.

Display-action patterns were determined for the three subspecies of S. horridus from 287 filmed displays performed by 34 individuals from 10 localities. Subspecific and geographic variations were apparent in their displays. Most unique was that three different display-action patterns were fixed in the species, two in each subspecies. Many individuals performed either pattern at random. This is the first report of significant pattern variations fixed within the display of individual lizards as well as the species.

****

DAVIS, JOHN D. (Miss. State U. for Women) and CRAWFORD G. JACKSON, JR. (San Diego State College). The comparative courtship behavior of Chrysemys concinna suwanniensis and Chrysemys scripta elegans.

The courtship displays of the Suwannee cooter, Chrysemys concinna suwanniensis and the red-eared turtle, Chrysemys scripta elegans were analyzed by high-speed videotape and photographic procedures. Fixed action patterns involving the forelimbs and foreclaws of the male were identified and described. Detailed examination and analysis reveals that a complex and highly stereotyped courtship display exists in the two species. Distinct male postures were described and analyzed quantitatively. It is suggested that the complex motor patterns involving the sexually dimorphic foreclaws of the males may have evolved from signal functions transferred from the jaws to the forelimbs. The biosystematics of the genus Chrysemys suggest that such studies may be of value in understanding taxonomic affinities and micro-evolution within this group.

****

DELSON, JEFF and WALTER G. WHITFORD (New Mexico State U.). Physiological comparisons of desert and montane populations of Ambystoma tigrinum.

Studies on the comparative ecology of montane and desert populations of Ambystoma tigrinum over the past three years in Southern New Mexico demonstrated marked differences in microhabit utilization and life history suggesting possible physiological adjustments in these populations. Field observations on a desert population under conditions of pond drying suggested that these animals might have higher thermal tolerance and dessication limits than montane environments.

Measurements of the critical thermal maxima (CTM) of these populations showed that large neotenic forms from the desert had a significantly higher CTM than those from the mountains while the reverse was found in larva of smaller size. Desert neotenic and larval forms had significantly higher CTM than did transformed individuals of the same size class. There was no significant difference in vital limits of dessication between small and large transformed adults. However, a signiticant difference in per cent weight loss was noted between animals dessicated in the laboratory and those dessicated under "natural" conditions.

Preliminary studies on the body chemistry of adults after one month in a terrestrial environment showed a significantly higher concentration of serum milliosmolytes and serum urea.

DIXON, JAMES R. (Texas A & M U.). Natural hybridization between Bachia intermedia and Bachia barbouri (Sauria: Teiidae).

Abstract not received.

****

DOWLING, HERNDON G. (Amer. Mus. Nat. Hist.). Comments on boid (Serpentes) relationships.

Several lines of approach in recent years have suggested that the division of the Family Boidae into "pythons" and "boas" is overly simplistic. Robert Hoffstetter (1946) was among the first to point this out, and he was followed by L. D. Brongersma (1951), A. S. Romer (1956), Garth Underwood (1967), and others.

Most of the information offered to date has served to split off one or a few genera into smaller groupings, but none has been well defined. Recent information on chromosome type and hemipenis morphology give additional information on relationships.

A large group of boids, including both "pythons" and "boas" proves to have a characteristic karyotype. However, Corallus on one hand and Eryx on another have distinctive chromosome patterns. The relationships suggested by hemipenis morphology also cuts across the "boa-python" border. A completely redrawn pattern of boid relationships may ensue from this new information.

****

ECHELLE, ANTHONY A., ALICE F. ECHELLE (U. Oklahoma) and HENRY S. FITCH (U. Kansas). Aggressive behavior among Costa Rican anoline lizards.

The aggressive displays of six species of Costa Rican Anolis will be described. Sympatric pairs of species were distinctly different in both of two important components of anole display: (1) the display-action-pattern, and (2) the nature of the dewlap. The dewlaps of sympatric species differed in all of three characteristics -- color, size, and shape. Regression analysis of dewlap area versus body-size appears to be useful in studies of the interrelationships between ecological factors and the nature of the display.

****

ECHTERNACHT, ARTHUR C. (Boston U.). Geographic variation of Ameiva undulata (Sauria: Teiidae).

Geographic variation among 45 samples drawn from throughout the range of Ameiva undulata in Mexico and Central America was studied utilizing a modification of Gabriel's Sums of Squares Simultaneous Test Procedure (SS-STP). Approximately 25 characters of scutellation, color and pattern were examined. Clines are numerous and most of them parallel the essentially linear form of Middle America. There appears to be a "Tehuantepec X" similar to the "Panamanian X" of Dunn in that clines for various characters cross the isthmus in both directions. Ameiva undulata tnomasi Smith and Laufe is synonymized with A. chaitzami Stuart, and the placement of A. festiva miadis Barbour and Loveridge in the synonymy of A. undulata is supported.

****

EDWARDS, STEPHEN R. (U. Kansas). Analysis of discontinuous variation in the Central American snake Scolecophis atrocinctus (Colubridae).

Specimens of Scolecophis atrocinctus were examined for variation in a number of characters. Basic statistics were calculated followed by univariate and multivariate statistical analyses to establish levels of significance in highly variable characters. It was determined that two distinct phena were contained in the species.

****

ESTES, RICHARD (Boston U.) and OSVALDO A. REIG (U. Central Venezuela). The Fossil Record of Frogs: A Review of the Evidence.

The fossil record of frogs is limited. Although some very significant finds have been made, few Triassic and Jurassic deposits are known of the type likely to contain frog fossils. Wide-spread aridity indicated in Triassic sediments and the paucity of Jurassic continental deposits probably will always combine to make recovery of extensive frog fossils unlikely. Since presently known Jurassic frogs are in great part rather closely related to modern forms, late Paleozoic and Triassic fossils are especially needed to clarify the early evolution of the group.

Current work in frog phylogeny has made little use of the existing fossil record. Since interpretation of several Mesozoic frog fossils has been subject to differences of opinion, the usefulness of this paper has been felt to lie in resolving some of these differences and in evaluating some of the character-states found in the most important forms.

The following are the major problems that will be dealt with in the symposium paper. Space limitation prevents discussion of these problems here.

1. Doleserpeton and lissamphibian ancestry
2. Triadobatrachus as a frog ancestor
3. Vieraella, the earliest known frog (early Jurassic) and its relationships
4. Notobatrachus and its position in frog evolution
5. The Paleobatrachidae and their fossil record
6. Major diversification of frog families
7. Problems in the study of fossil frogs

GUTTMAN, SHELDON I. (Miami U. Ohio). Biochemical Techniques and Problems in Anuran Evolution.

In recent years, systematic evaluation of groups of organisms has been facilitated by the use of non-morphological techniques. One of the newest of these techniques, biochemical analysis, has been of great value in corroborating, and in some cases, modifying, phylogenies of Drosophila, coleopterans, primates and certain plants.

Few biochemical studies of anurans have been made. These analyses have determined patterns of integumental pteridines, parotoid gland secretions, general skin venoms, blood proteins and organ homogenates. Chromatographic, electrophoretic and serological techniques have been employed. Results of these studies indicate individual variation, polymorphism, interpopulation variation, species specificity and some higher order relationships. The absence of a trend in any biochemical system examined is evident; this may be due to investigations being few in number, non-uniform techniques being utilized and/or a lack of concentrated effort by biochemical systematists to supplement findings based on other non-morphological and morphological methods.

Future biochemical work, if properly oriented, can be of great value in determining anuran phylogeny. Sophisticated quantitative procedures, such as microcomplement fixation, are presently available to evolutionists for use in clarifying difficult problems of relationship at all anuran taxonomic levels.

****

LYNCH, JOHN D. (U. Nebraska). The Transition from Archaic to Advanced Frogs.

Early classifications of the anurans sought to cite the distinctions between living groups rather than to point out their similarities. In any classification both qualities are needed in order to have a realistic classification. The arrangements proposed by Cope, Boulenger, Noble, Orton, Hecht, Griffiths, Inger, and Kluge and Farris suffer from the small number of characters employed and with the exceptions of the last few, suffer from stressing one or two characters as "more fundamental" for interpreting phylogeny.

The characters employed and their weighting are the basis of any classification. The one proposed here employs 34 equally weighted characters, 22 of which are osteological, five myological, three larval, and four additional non-osteological. Primitive character-states are scored 0, derived states 2. Scoring each character equally, the sums for each of approximately 40 family groups may be compared: low values reflect the retention of more primitive character-states whereas high values reflect the retention of few primitive character-states and the acquisition of more derived (advanced) states.

Three levels of organization are apparent: (1) Ascaphidae and Discoglossidae, (2) Pelobatidae, Pelodytidae, Cycloraninae, and Heleophryninae, and (3) all other frogs including pipids and some leptodactylids at the base and the microhylid groups at the apex. This arrangement is an evolutionary grade and fails to account for cladistics. It does point out that pipids and rhinophrynids are not appropriately included in the "archaic frogs." Characterizing archaic and advanced frogs is difficult when many characters are employed because it ignores the transitory groups (Pelobatidae and Old World leptodactylids) and the division attempts to include pipids and rhinophrynids as archaic frogs. If we insist on formal recognition of Archaic and Advanced frogs, the only Archaic frogs are the Ascaphidae and Discoglossidae.

A small group like the Anura is unduly burdened by suborders. I propose that supratamilial groups be denoted by superfamilies. Thus the Ascaphoidea includes Ascaphidae and Discoglossidae, the Pelobatoidea includes Myobatrachidae (Old World "leptodactylids"), Pelobatidae, Pelodytidae, Rhinophrynidae, and Sooglossidae, the Pipoidea includes Pipidae, the Bufonoidea includes Bufonidae, Centrolenidae, Dendrobatidae, Hylidae, Leptodactylidae, Pseudidae, and Rhinodermatidae, and the Ranoidea includes Microhylidae and Ranidae (tentatively including Hyperoliidae and Rhacophoridae).

****

MERRELL, DAVID J. (U. Minn.). Ecological Genetics with Anura.

Ecological genetics stems from the union of population genetics and population ecology. It is the study of the ways in which natural populations are adapted to their physical and biological environments, and the mechanisms by which populations respond to environmental change.

The burnsi and kandiyohi polymorphisms in the leopard frog, Rana pipiens, were chosen in order to study some of the theoretical and mathematical concepts of population genetics and population ecology in natural populations. Both field and laboratory studies were conducted.

The results of these studies gave a clearer picture of the distribution and frequency of these dominant genes in the Upper Midwest. Heterosis has been shown to be an unlikely explanation for the polymorphisms. Instead the burnsi type appears to survive the winter somewhat better than the wild type pipiens, and kandiyohi, which seems confined to the prairies, seems to metamorphose earlier than pipiens, an adaptive advantage where breeding ponds tend to dry up prematurely.

Other studies have demonstrated natural selection against a deformity, and have permitted a comparison between population size based on mark-recapture data and Wright's "effective size" of the breeding population based on egg mass counts.

****

MILSTEAD, WILLIAM W. (U. Mo.-Kansas City). Toward a quantification of the ecological niche.

The suggestion is made that a finite number of broad ecological niches exist in any biome type, and that these niches may be defined by comparisons of ecological equivalents from different continents. Biological points of comparison should include ecology and physiology as well as morphology.

MINTON, SHERMAN A. JR. and SYLVIA KENDALL SALANITRO (Ind. U. Med. Cntr.). Further Studies on Serological Relationships among Colubrid Snakes.

Sera of 22 species of colubrid snakes were studied by immunoelectrophoresis using antisera against Coluber constrictor, Elaphe vulpina, Natrix sipedon, Naja naja and Crotalus horridus to develop the preparations. Development of a snake serum with its homologous antiserum gives a pattern of seven or eight precipitin arcs. Some of these represent components widely shared among snakes while others are more or less specific for closely related taxa.

Two serological groups can be distinguished in our material. One consists of Elaphe (3 sp.), Lampropeltis (2 sp.) and Pituophis melanoleucus. The other consists of Natrix (4 sp.), Thamnophis (2 sp.), and Regina septemvittata. Serologically these groups are as distinct

from each other as they are from Naja and Crotalus. Coluber constrictor is somewhat intermediate between the two but closer to Elaphe. Four Old World colubrids, Coluber jugularis, C. ravergieri, Spalerosophis diadema and Malpolon monspessulanus, are serologically intermediate between Coluber constrictor and Elaphe. Psammophis schokari, Trimorphodon biscutatus, Leptodeira maculata, and Heterodon platyrhinos do not fit either of the above groups nor do they appear to be closely related to one another.

PURDUE, JAMES R. (U. Oklahoma). A comparative study of the body movements of displaying males of the lizard genus Sceloporus (Iguanidae).

Males of the species of the genus Sceloporus display by performing a series of push-ups involving their forelegs and, to varying degrees, their hindlegs. The amount of shoulder and hip movement per push-up was quantified by calculating two ratios: one by dividing the vertical shoulder movement by the vertical eye movement, and the second by dividing the vertical hip movement by the vertical eye movement. Each of the 21 species analyzed had a characteristic mean hip ratio. Interspecifically there was a highly significant positive correlation coefficient between the mean shoulder and hip ratios. Species that had much hip movement also had much shoulder movement.

Another significant, but negative, correlation was between the mean hip ratios and the mean snout-vent lengths. This relationship was attributed to a general compensation for the proportionately greater weight of the larger species. Further analysis indicated that the amount of hip movement was not merely an individual response to the weight/length relationship. Rather it was a genetic response by the species with closely related species having similar amounts of hip movement.

RABB, GEORGE B. (Chicago Zool. Park). Evolution of Mating Behavior.

Abstract not received.

****

SALTHE, S. N. (Bklyn. Coll. C.U.N.Y) and WILLIAM E. DUELLMAN (U. Kansas). Evolution of Reproductive Adaptations.

Salthe found close relationships between ovum size, body size, and clutch size in urodeles. Anurans have a much more complex spectrum of life histories so that it is of interest to see whether these relationships obtain with them as well.

Ovum size correlates positively with female body size, but not in a simple way for all frogs. The correlation is clearly apparent only within single modes of reproduction (composite of site of development and mode of development). Even then the correlation is not perfect because clutch size varies to some extent independently, so that the correlation is best with total clutch volume. Thus, many Rana and Bufo have essentially the same modes of reproduction, but Rana ova are generally larger than those of Bufo within a given adult size class while the clutch sizes of Bufo tend to be larger. Within any size range of female body size ovum size and clutch size are inversely correlated. Clutch size also correlates with female body size, but again this is most clearly apparent within a single reproductive mode.

One can approach ovum size also from the ecological point of view, emphasizing the site of development instead of female body size. There is evidently some necessity for having larger eggs in stream situations or in terrestrial nests and smaller ones in association with standing water. In the latter case we may be seeing the results of selection for larger clutch sizes (increased genetic variability per reproduction). In streams and terrestrial situations, however, larger tadpole or hatchling size becomes important. Size at hatching can only be increased by increasing ovum size. We can also combine site of development, ovum size, and female body size in one correlation. Again, ovum size increases with female body size but clearly so only within a given site of development. Within a species there is much data showing increased clutch size with increased female body size, but very little indicating an increase in ovum size with female body size.

Although within a species larger ova tend to respire at higher rates than smaller ones, an increase in ovum size phylogenetically is associated with lowered developmental rates, and so a change in ovum size, say in connection with stream adaptations, exacts a price in slower development, which might in turn make necessary less accessible nesting sites, such as the branches of overhanging trees.

Increased ovum size, of course, cuts fecundity for any given reproduction. In the tropics or subtropics, where this has frequently occurred, there is another aspect of the life history strategy that can be varied to compensate for this - the number of times a female will breed in a year. Ovum size could perhaps only be increased in some cases if it were possible also to increase the number of different times a female ovulated in one year.

In short, all aspects of reproductive strategies are interconnected to produce a single whole. One parameter, such as ovum size, is for this reason found to correlate with all other parameters. This interconnectedness must also impose limits on change or reproductive mode in that all aspects must change together simultaneously.

SAVAGE, JAY M. (U. So. Calif.). The Geographic Distribution of Frogs: Patterns and Predictions.

The present distribution of 43 families and subfamilies of frogs falls into five major patterns: a) northern extratropical; 4 groups b) cosmopolitan tropical; 2 groups, c) wide-spread tropical; 3 groups, d) tropical; 27 groups, and e) southern extratropical; 6 groups. The groups contribute in various degrees to form 5 major world frog faunas; the Holarctic, the African, the Malagasian, the Australasian and the South American. The Indo-Malayan region forms a transitional area between Holarctic and Australasian frog faunas. When these patterns are correlated with known aspects of evolutionary relations, the fossil record and paleoclimatic associations, it is evident that three major frog lineages were present by earliest Jurassic and the fourth by the end of that period, that most families of frogs were present by mid-Cretaceous, that present distribution patterns are Cenozoic modifications of those established in Mesozoic and that the patterns are best explained in terms of the concepts of continental drift and the history of the two super continents of Mesozoic, Laurasia and Gondwanaland.

Five major historical source units are recognizable on the basis of these data:

OLD TROPICAL - derivatives of groups distributed in tropical regions of Laurasia and Gondwanaland by early Jurassic, disjunct circumtropical distribution today (e.g. caecilians, pipids and microhylids).

LAURASIAN - derivatives of stocks established in Laurasia by Jurassic and associated with Eurasia and North American throughout history; circumpolar during much of Tertiary but fragmented by cooling and drying trends in late Cenozoic (e.g. salamanders, ascaphids, discoglossids and pelobatids).

ANTIBOREAL - a group of frogs (Leiopelmatidae) known from Jurassic onward in extreme southern Gondwanaland and its fragments.

YOUNG TROPICAL - derivatives of groups that evolved in tropical areas of the western Gondwanaland continent by early Cretaceous; in Cenozoic developing extensive tropical radiations and expanding onto Eurasia and North American (e.g. bufonids and ranoids).

SOUTH GONDWANIAN - descendents of a southern extratropical group that became fragmented by continental drift onto several land masses derived from Gonwanaland; in Cenozoic radiating northward into tropical America and Australasia (e.g. leptodactyloids, hylids, nyctimystids, dentrobatids).

The fundamental pattern of amphibian distribution is derived from two primary sources: 1) the ancient establishment, by early Jurassic, of two major centers of evolution, one on the northern Laurasian land mass (salamanders, some xenoanurans, lemmanurans and pelobatids) and another on the southern Gondwanaland supercontinent (caecilians, pipids, microhylids and advanced acosmanurans); 2) the fragmentation and evolution in isolation during Cretaceous of caecilians and frogs on the six land areas derived from Gondwanaland and of salamanders and northern frogs on Laurasia. Contrary to the ideas of Darlington (1957: 158) frog evolution has not been centered on the Old World tropics. Substantial distinctive radiations of microhylids and acosmanurans have taken place in each tropical area, except on the Indian Island where caecilians and microhylids developed in a unique fashion. In Africa the radiations involved caecilians, microhylids, bufonids and ranoids; in Australasia microhylids, myobatrachids and nyctimystids; and in South America microhylids, bufonids, hylids and leptodactylids. The basic stocks for the radiations of leptodactyloids and their derivatives in Australasia and South America were

temperate adapted groups that invaded subtropic and tropical regions from the south. The tropical areas of India and south-east Asia have never been a major source region for frog evolution and radiation, but serve as a refuge for tropical Asian groups displaced southward by cooling late Cenozoic trends and the ancient Indian caecilian and microhylid stocks that developed while the sub continent was a Cretaceous and early Tertiary island. In Cenozoic, the connections established between several southern land masses and northern regions allowed invasion of North America and Eurasia by southern tropical lines. The most successful radiations were by bufonids and hylids from South America and by ranids from Africa.

These groups have followed the northern land masses as immigration routes, the former two families into Eurasia from North America, and the latter to North America from Eurasia. Bufonids subsequently have moved southward from northern Asia into India and Indo-Malaya and ranids have now reached South America. Remnants of the ancient fauna of Laurasia still persist in Eurasia (salamanders, discoglossids and pelobatids) and North America (salamanders, Ascaphids and Rhinophrynids). The peculiar endemic genus Leiopelma of New Zealand is a relict of an ancient temperate Gondwanaland radiation. The most consistent theme of amphibian evolution is the unique quality of radiations on each Gondwanaland derivative land mass; the role of pre-emptive occupancy of ecologic (adaptive) zones as limiting their composition, rather than competitive replacement; and growth and increasing diversity through addition of new groups that coexist with earlier stocks.

SAVITZKY, ALAN H. and HOBART M. SMITH (U. Colorado). Concerning the taeniata group of the genus Tantilla (Serpentes: Colubridae).

Three additional members of the taeniata group of the colubrid snake genus Tantilla are recognized. T. cuniculator, from the Yucatan Peninsula is referred to the taeniata group; it may also bear evidence concerning the identity of T. trilineata. T. cuniculator and a new species from the Atlantic versant of Oaxaca represent the only known bilineate members of the otherwise trilineate taeniata group. The bilineate species from Oaxaca, known from a single specimen, is further characterized by the retention of only remnants of the lateral light stripes and by an extremely high ventral count. It appears to be most closely related to T. taeniata. A new trilineate species, also from the Atlantic versant of Oaxaca and represented by a single specimen, differs from other members of the taeniata group in having a narrower dark field ventral to the lateral light stripe. It, too, appears to be most closely related to T. taeniata. A general trend toward loss or obscuring of the light stripes is evident in the taeniata group, and has occurred polyphyletically. Evolutionary and distributional patterns within the taeniata group present problems of interpretation.

SCHIOTZ, ARNE (Danmarks Akvarium). Evolution and Mating Call: Ecological Considerations.

Until recently evidence for the function of the mating call in Anura has been incomplete and sometimes contradictory, as stated by Bogert 1960. A number of observations in later years have shown definitely, however, that in many species an important role of the mating call is that the female during part of the reproductive cycle is positively attracted to a calling male of its own species. This does not seem to be the case during the migrating period, or the pre-spawning period, present in some species, but only in the beginning of the spawning period. Observations have also shown that females seem indifferent to voices of other, even closely related species, so it is undoubtedly correct to conclude that the mating call plays an important role as an isolating mechanism in the Anura. Observations (Brattstrom) seem to show that there is also an element of competition between males, the dominant male in the chorus structure having the largest chance of reproducing. Finally, the mating call possibly also has a territorial function.

Experiments or reliable observations showing that the mating call plays other roles, for instance in forming breeding aggregations, seem to be lacking.

It is thus to be expected that the function of the mating call as an isolating mechanism will tend to keep it as stable as possible within a taxon, while the competition between males will encourage an evolution of the call within the taxon.

In accordance with their role as isolating mechanisms, the mating calls of sympatric species seem always to be distinct from each other. Examples of character displacement in voices has been recorded (Blair, Littlejohn).

Generally speaking the voices of species within a genus are similar - a rule with many exceptions. Genera within a family, however, do not seem to have similarities in voice not shared with genera from other families.

On the intraspecific level - subspecies within a species and species within a superspecies - the difference between voices is very small, often, but not always, smaller than the morphological differences in the three sets of characters; habitat preference, voice, and morphology in a number of polytypic species within the African genera Leptopelis and Hyperolius. Apparently habitat preference is the most stable character with a number of closely related forms, voice less constant and morphology and colour pattern even less. If we thus, for a systematical group, attempt to base a zoogeography on morphology and compare it with one based on voices, we will see that the zoogeography based on morphology gives the finest subdivisions; there is perhaps a tendency that the more recent geographical barriers are shown only in morphology, the older in morphology and voice. Other groups (e.g. Crinia in Australia) will show a different pattern.

Apart from the strong tendency for voices within a genus to be similar, there is perhaps another, much weaker, tendency for the voices in similar habitats to be similar. This is a very doubtful trend, but it seems to be the case for the African frogs breeding in temporary pools in dense forest. A majority of these have a characteristic, quiet voice. Also the voices of a number of species which do not form breeding aggregations seem to have common characters, being high pitched, insect-like screams, which have perhaps developed as a result of the difficulties encountered in tracing these voices.

A number of mute forms are found in widely different systematical groups. Generally they do not seem to occur sympatrically with closely related forms, and therefore do not need the voice as isolating mechanism.

An attempt to get an impression of the evolution of the mating call by comparing mating calls within the different systematical groups of Anura does not give much result. The primitive Leiopelmidae have no vocal sac and no voice, and the primitive Pipidae lack a vocal sac but have a primitive mating call. In both cases it seems doubtful whether we have a true primitive character or rather an adaptation to the mode of life in these families. The remaining Anuran families seem all to have highly developed voices.

****

STARRETT, PRISCILLA H. (U. So. Calif.). Evolutionary Patterns in Larval Morphology.

The importance of larval characters in determining anuran phylogeny is the subject of much controversy. I believe this controversy has resulted from interpreting external characters without adequate knowledge of the internal morphology. The position of the spiracular openings in anuran tadpoles has increased significance when related to the structure of the branchial chambers and the position of the forelimbs. Comparative embryological studies show that all larvae have bilateral openings at some stage in their development. The operculum grows posteriorly and medially at different rates to produce the final distinctive types. This is evidence of the primitive nature of bilateral spiracular openings. The chondrocranium, jaw cartilages and jaw musculature also show differences in major groups of anurans.

The first group, Xenoanura, is characterized by two separate branchial chambers with two external openings and the forelimbs developing posterior to the chambers. The jaw cartilates are simple with no separate infralabial cartilages. Feeding and respiration involve essentially the same actions and utilize the same mandibular and hyoid muscles.

In the second group, Scoptanura, two separate branchial chambers, having two internal apertures are connected to the exterior by a single opercular tube opening ventrally. The forelimbs develop posterior to the gill chambers, also. Respiration and feeding are similar, but a small separate infralabial cartilage along with a unique mandibular muscle enables these tadpoles to feed on infusoria by means of a protrusible lower jaw. These two groups feed on microorganisms and many species are efficient filter feeders.

The other two groups of tadpoles are characterized by the development of a long coiled gut necessary for algae digestion. Related to this is the development of an upper jaw cartilage and modification of the lower jaw cartilages producing an extra joint and a more flexible functional

mouth. Modification of the mandibular and hyoid musculature accompany this feeding specialization. The branchial area is reduced and appears to have been "pushed" anteriorly by the much larger gut. A single median spiracle or a sinistral spiracle are two different ways of increasing the efficiency of the respiratory and filtering surface of the gills. The Lemmanura have separate branchial chambers opening with a single mid-ventral spiracle. The forelimbs develop very close to the posterior peribranchial ectoderm. The Acosmanura have the original two branchial chambers connected by a ventral communicating channel producing a functional single chamber. This usually has a sinistral opening. In this group the forelegs develop within the branchial chamber.

The position of the spiracle is related to hydrodynamic balance. It is a decided advantage to a mid-water feeder to have either bilateral spiracles or a single ventral opening as the excurrent flow of water exerts a force which affects the positioning of the tadpole. In addition, the shape of the tail fin and presence of a terminal filament are important factors in maintaining a desirable feeding position. A sinistral spiracle is more advantageous in bottom feeding as the excurrent siphon is not obstructed.

The development of accessory mouth structures: shearing beaks, denticles and papillae have enabled the tadpoles of acosmanuran frogs to occupy a myriad of niches. The adaptations are usually related to specific habits and any generalizations should be made with caution. For example, expanded lips can produce an adhesive mouth structure enabling tadpoles to live in fast moving water. However, rheophilous tadpoles occur with abdominal adhesive discs or without any modifications for clinging. Large lips are also used for surface feeding and for sweeping in food. Increased numbers of denticle rows occur in some forms with adhesive mouths but also may be used for grasping prey by carnivorous animals. Other tadpoles have greatly reduced lips. The numerous specializations allow many aquatic habitats to be utilized.

In contrast, the more primitive tadpole of the scoptanuran frogs is successful primarily in the tropics and has developed very few major variations in structure. Various types of non-aquatic development occur in many families of frogs. In the microhylids this has been an especially important factor in overcoming the limitations of the tadpole.

Although there is considerable variation in some of the superficial characters, the basic internal morphology of the tadpole remains much more constant.

****

STRAUGHN, IAN (U. Coll. Townsville). Evolution of Mating Calls: Bioacoustical Considerations.

Studies of anuran mating calls have played a significant role in understanding systematics and evolution within the order, particularly in defining species and their inter-relationships. Except for the most primitive members of the order, voiceless frogs have arisen secondarily. Indeed, the extant primitive species could also be remnants of voiceless derivatives of the earliest frogs which for the most part were vocal but have been replaced by more advanced forms. The phylogentic origin of mating calls is so old it cannot be established with any certainty, but it would seem that vocal communications of some form have been present since the origin of the group.

Within the order there has been considerable divergence of call characters and the behavioral function of the acoustic communication systems. Electronic analysis and precise description of mating calls have greatly enhanced their use as taxonomic tools. However, their use above the species group, or, at most, generic level has been suspect. Looking at so called "mating calls" in the context of communication systems rather than just describing the calls per se may provide information that is more useful in examining higher taxonomic categories.

By defining these communication systems, categorizing them as primitive, advanced or derived on the basis of communication theory (independently of established phylogeny), a new insight into higher taxa and their relationships may be gained. So little information is presently available on the functionality of anuran communicative systems that such an analysis must be largely speculative. However, by using the information available from the small sample within each family on which there are data, inter-familial relationships can be postulated.

TAYLOR, DOUGLAS H. (U. Notre Dame). Effect of cyclic injections of melatonin on the biological clock of larval Ambystoma tigrinum.

Research in birds and mammals has implicated the pineal system in the control of biological clocks and testicular recrudescence. Although the mechanism of stimulation may differ, control seems to be exerted through the cyclic production of melatonin (5-methoxy-N-acetyltryptamine) which is synthesized from the O-methylation of N-acetylserotonin by acetylserotonin methyltransferase in response to light.

Preliminary evidence from studies of Ambystoma tigrinum larvae, kept in constant light and in constant dark, supports the hypothesis that a similar system is operative in these amphibians. Daily injections of melatonin, administered at 1200 each day for 3 days via a flow-through system, can serve to rephase the biological clock of these animals and to shift their expected orientation direction by approximately 90 degrees. This suggests that melatonin may be the chemical transducer for biological clock control.

****

TAYLOR, EDWARD H. (U. Kansas). Squamation in caecilians.

The primary purpose of materials impervious to liquids, at or near the surface of the body surface of organisms, is usually for control of moisture acquisition or loss. The material may be bone, scales, or modified skin; the control may be by means of slime secretions that make the surface wholly or partially impervious.

Caecilians originally may have depended chiefly on materials now covered by skin, which are designated scales or squamae. The number of rows around the body may exceed a thousand. The greatest coverage is on species that are regarded as the most primitive. In certain forms, perhaps more recently evolved, the scales may be reduced to one or two rows near the terminus of the body, or they may have altogether disappeared. The trend of loss is from fore to aft. Certain families are wholly without scales; in one scales are present in all forms; and in still another the scales are present in some forms, absent in others.

The question as to whether the character of the scales differ sufficiently to be used as a taxonomic aid is considered, with the conclusion that while not wholly practical they may so serve.

****

TRUEB, LINDA (U. Kansas). Bones, Frogs, and Evolution: A Phylogenetic Dilemma.

Commencing with Cope and Boulenger in the nineteenth century, osteological features became pivotal characters in the classification of anurans. The classification has been revamped repeatedly and modern methods utilizing statistical techniques and computer technology allow the researcher to interject more and more characters in ever increasing detail into programs designed to diagnose evolutionary relationships. Nonetheless, the osteological criteria employed have been refined only slightly in the intervening 100 years. This is in a large part due to the lack of interest expressed in descriptive morphology during the past three decades. Generic monographs and species descriptions have tended to stress obvious, external traits and slight osteological characters. This is unfortunate because often the skeleton is a source of many distinctive features at the generic and specific levels. There is considerable information available on some of the more distinctive groups such as the ascaphids, discoglossids, and pipids, and of course, Rana. However, for the majority of anurans, osteological information is scanty and highly divergent with respect to its quality and thoroughness; such circumstances discourage attempts to synthesize information and clearly indicate the need for basic osteological investigations at the family, generic, and specific levels.

Proper evaluation of osteological characters and their evolutionary significance is contingent upon an understanding of the nature of the tissue involved and its capacity for modification. Bone has classically been thought to arise from one of two sources, either from membranous connective tissue or cartilage; these two types are known as membrane or dermal bone, and endochondral or cartilage bone, respectively. Until relatively recently, it was conceeded that the two types were unrelated and characteristically gave rise to particular elements. Recent evidence strongly suggests that the two bone types are not independent, but instead represent extremes of a continuum which embraces a variety of bone formations derived from either one or both sources. There is good evidence to indicate that in the course of evolution centers of ossification are capable of migration to produce fusions of formerly discrete elements. Furthermore, it has been shown that new centers of ossification appear in response to need for additional bone. Heterochrony acts to arrest development of bone and produce apparent reversals

in the occurrence of primitive or paedomorphic characters in otherwise advanced anurans. In summary, osteological features are a great deal more labile and subject to considerably more variation than has been thought by previous workers.

A synthesis of the extant information on anuran osteology has suggested several generalized evolutionary trends. There is a trend towards reduced ossification and reduction of the number of component skeletal elements among modern anurans. Addition of dermal elements, marked expansion and modification of existing dermal elements, and synostosis of endochondrally and dermally derived elements, can usually be interpreted as specializations. Modifications of the first two types frequently concur with marked reduction elsewhere in the same architectural unit. There apparently is an upper limit to the amount of bone that can be involved in any given supportive system, although there is no evidence that the converse is true. The greatest reservoir of evolutionary change lies in the typical dermal components of the anuran skeleton system; endochondral elements, by comparison, are more conservative. Dermal elements, and to a lesser extent endochondral elements, are frequently subject to adaptive modifications; similar modifications may appear independently in several groups.

Several more specific evolutionary patterns have emerged from this study, as follow: The anuran cranium is characterized by consolidation of ossification centers and cranial nerve foramina, reduction in the width of the premaxillary, and repeated, independent loss of the quadratojugal, palatine, and prevomer. Addition of bone externally is countered by reduction of bone internally. The function of the pterygoid has tended to shift from that of a palatal bone to that of a suspensory element. The evolutionary sequence of dermal modification follows an obligate pattern which commences with exotosis and may progress to casquing and terminate with co-ossification. The hyoid tends to remain cartilaginous and have smaller, less elaborate ancillary processes. There is a notable trend towards development of firmisternal-like pectoral girdles; modification of the arciteral condition is usually accompanied by loss of the procoracoid, reduction of the clavicle, elaboration of the scapula and pre- and postzonal elements, and reduction in the length of the pectoral arch. The cervical cotyles tend to become laterally displaced, and transverse processes of the presacral vertebrae tend to become equivalent in width to one another and the sacral diapophyses. Primitively, the sacral diapophyses are broadly expanded; they tend to be reduced in length among advanced anurans. The pelvic apparatus shows a trend towards morphological elaboration whereas the appendages demonstrate fusion and loss of component elements.

****

VIAL, JAMES L. and JAMES R. STEWART (U. Mo.-Kansas City). Comparative studies on activity patterns of Desmognathus quadramaculatus and Leurognathus marmorata.

Field studies in the southern Appalachian Mountains were correlated with those conducted in controlled environmental chambers. Both D. quadramaculatus and L. marmorata exhibited substantial daytime activity, although light may not be the initiating cue in the latter species. In constant darkness both species demonstrated a trend to arrhymicity from their normal activity cycles. Desmognathus frequently occupies deep burrows whereas Leurognathus does not; however, a relatively greater amount of foraging behavior is characteristic of the more aquatic Leurognathus. No temporal isolation was detected between specific activity patterns.

****

WASSERSUG, RICHARD (U. Calif.). Ecological and Behavioral Patterns of Anuran Larvae.

Gregarious behavior patterns in anuran larvae have both ecological and evolutionary implications. Certain tadpoles form non-oriented social aggregations, showing mutual attraction - approach. In addition parallel orientation may be present at times (i.e., true schooling in the sense of Shaw, 1970).

Partitioned clear plastic trays were used to measure statistically the aggregating tendencies of various tadpoles. Xenopus laevis, Rhinophrynus dorsalis and Bufo boreas all exhibit a strong ($.99<p$) mutual approach response. Rana pipiens also exhibits this response ($.90<p$) but it is absent in Rana boylei, Hyla regilla, Scaphiopus hammondi and Ascaphus truei (at both 8° and 23°C).

Elements of schooling behavior are evident in the optomotor response of fish. Tadpoles, therefore, were tested in an optomotor apparatus similar to those used to study this phenomenon in fish. Xenopus laevis, Rhinophrynus dorsalis, Hyla regilla, Rana pipiens, R. catesbiana, R. boylei and Bufo boreas showed a significantly strong tendency to orient in the direction of the moving drum and to swim at the speed of drum rotation. Ascaphus truei did not (8° and 23°C).

The aggregating behavior of the tadpoles in the plastic trays is consistent with knowledge of their ecology. Tadpoles of Bufo boreas, Xenopus laevis, and Rhinophrynus dorsalis all form natural, dense aggregates. Stream forms, like Ascaphus truei and Rana boylei do not, perhaps because it is energetically difficult to maintain group integrity in a current. The optomotor response seems to be nearly ubiquitous in tadpoles. Its absence in Ascaphus truei may be a specialization correlated with the habit of substrate adhesion in dark, fast-flowing streams. Ascaphus tadpoles have well-developed lateral line systems and eyes positioned so as to preclude effective lateral vision. The specialized behavior of Ascaphus tadpoles does not support Schmalhausen's (1964) view of this tadpole as the generalized tadpole ancestral type.

Tadpoles that show true schooling mostly fit into two classes. Xenopus, certain hylids and microhylids typically form midwater schools. These tadpoles are often specialized filter-feeders with eyes far lateral, a rapidly beating tail filament, reduced pigmentation and a symmetrical spiricular pattern. Shallow water and bottom schools are more common. This pattern is typified by Bufo tadpoles which are not as efficient at filter feeding and tend to be dark colored with eyes dorso-lateral. They form closely packed, slow moving or stationary schools. There is some evidence that gregarious Bufo tadpoles are unpalatable to vertebrate predators. Examples of non-Bufo tadpoles that form conspicuous dark aggregations are Hyla maxima (presumably actually H. geographica; vide Kenny, J. S. 1969 The Amphibia of Trinidad.--Ed.) and Leptodactylus melanonotus.

It is well-known that growth is inhibited in crowded tadpoles. Although Licht (1967) claimed this inhibition to be nonspecific, his data may be interpreted to show that tadpoles likely to form dense schools also tend to show the least amount of inhibition.

Interspecific and interfamilial behavioral patterns that correlate with ecology and morphology in tadpoles suggest that tadpole behavior may be valuable in understanding the evolutionary biology of the Anura. The possibility of kin selection and mimicry complexes among conspicuous aggregating tadpoles are two of the more fascinating problems that will not be solved until there is more comparative ecological data available.

****

WOOLLEY, H. PATRICK (E. Central Jr. Coll.). The ecology and distribution of Eurycea longicauda melanopleura and Eurycea lucifuga in western Missouri.

This study of E. lucifuga and E. longicauda melanopleura consisted of five parts: (1) distribution and ecology of the two salamanders in western Missouri, which is the western boundary of the known range, (2) establishment of reasons for their close association with limestone, and (3) caves, (4) reasons for segregation in many areas, particularly in caves, (5) development of a suitable method for marking salamanders other than the conventional "toe clipping."

A significant portion of this investigation pertained to interspecific competition. Both species were occupying similar niches in western Missouri. Interspecific competition probably causes them to segregate (87 of 105 caves in western Missouri which contained salamanders exhibited segregation). Utilizing Cole's (1949) "measurement of interspecific association" a negative .348 was derived indicating that interspecific competition is present. A Chi square value of ($P < 0.01$) indicates that this figure is statistically significant. In the eighteen caves which had integrated populations, interspecific competition for food occurred in the early spring when flooding within caves caused food to be dispersed more evenly throughout the cave. E. lucifuga were found to be more aggressive feeders than E. l. melanopleura in the laboratory. Approximately sixty per cent of the E. l. melanopleura salamanders methodically began dispersing themselves following flooding from areas of higher interspecies concentrations to areas on the perimeter where salamander concentrations were reduced.

The presumed reason for this dispersal of E. l. melanopleura salamanders is that they were existing in an area where competition was high and food densities were low. Following flooding, food was distributed more evenly, thus increasing food densities and reducing competition. As food was reduced within areas of the cave perimeter, E. l. melanopleura migrated to areas of higher food density and lesser competition outside the cave, followed by the progressive movement of E. lucifuga, which began to exhibit intraspecific competition.

****

WORTHAM, EDWARD and MAX A. NICKERSON (Arkansas State U.). A serum protein study of Ozark Cryptobranchus.

This study was to determine if disc electrophoretic patterns of serum proteins could be used to distinguish between populations of Cryptobranchus from north and south draining Ozark streams.

The serum from ninety Cryptobranchus, thirty from each of three populations, was subjected to electrical migration through polyacrylamide gels, following closely the procedures of Davis (1961).

The serum protein patterns of C. bishopi from south draining streams and C. alleganiensis from north draining streams were distinguishable when the serum protein patterns between 13mm to 20 mm of the middle zone of the separation gel were analyzed with regard to their migration rate. It is suggested that Cryptobranchus from the north and south draining streams of the Ozark Plateau may have been separated since late Tertiary and currently should be treated as separate species.

Other individuals present did not register.

CURRENT HERPETOLOGICAL TITLES, XIII: 1969 - 1970

Herpetological Information Search Systems
American Museum of Natural History
New York, N. Y. 10024

We have brought to your attention some 12,000 current titles in the pages of this journal to date. This list brings the titles of papers published in 1969 to a new high for one year, 4,118, and there are still more to go.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts-Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses especially.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any current paper (e.g., 1969-1970) that is concerned with a member of a Recent order of amphibians or reptiles.

HERPETOLOGICAL REVIEW will appear bimonthly, beginning in 1971. This means that the titles published here will be even more current. Further, the added issues will serve to reduce the titles-per-issue to a more manageable number.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This list contains titles of books and articles that have come to our attention during the period 8 October 1970 through 31 December 1970. The list is divided into two separate, alphabetically arranged sections: one for titles published in 1969, and one for titles published in 1970.

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and L. Greene. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. Dr. Robert W. Winter provided us with translations of titles, abstracts and papers from Slavic languages. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

Members of the Herpetology Department and the Library staff of the Museum have continued to aid our efforts. No commercial computer service yet offers all of the facilities that we need and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 29 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

HERPETOLOGICAL
INFORMATION
SEARCH
SYSTEMS

OFFERS:

COPIES of original descriptions or other important literature.

DRAWINGS of important taxonomic features.

CONSULTATION on projects involving amphibians and reptiles, their literature, morphology, ecology....

SPECIAL BIBLIOGRAPHIES on amphibians and reptiles, restricted by subject and/or taxon and/or geography.

"CURRENT TITLES" for 1971 on Library Cards, about one-third of them with abstracts. Also available for 1968, 1969, and 1970 (3,000 to 4,000 titles per year; Library of Congress stock, hole-punched, alphabetical).

BIBLIOGRAPHIES of individual authors.

CHROMOSOMES OF A NEW GUINEAN MICROHYLID FROG, COPHIXALUS RIPARIUS ZWEIFEL

C. J. Cole and R. G. Zweifel

The following is presented as a contribution to the extremely meager knowledge of karyotypes of the Microhylidae. The junior author obtained the specimen analyzed while participating in the Research Vessel Alpha Helix Expedition to New Guinea in 1969 (funded by the National Science Foundation through the Scripps Institution of Oceanography, University of California).

Chromosomes of 63 bone marrow cells at mitotic metaphase were examined on slides prepared by means of the colchicine, hypotonic citrate technique used by Cole, Lowe, and Wright (1968). The adult female frog, American Museum of Natural History (AMNH) 82987, was collected at Tambul, 7300 ft. elev., Western Highlands Dist., Territory of New Guinea, in July 1969.

In all instances, the diploid number of chromosomes was 26: 10 relatively large and 16 distinctly smaller. The metaphase-spread selected for illustrating the modal karyotype (Fig. 1) is the one illustrated in the 101st Annual Report of the American Museum of Natural History (1970: 8).

Of the five pairs of larger chromosomes, number 5 is clearly metacentric, number 1 is metacentric to submetacentric, numbers 2 and 4 are submetacentric, and number 3 is subtelocentric. Although numbers 2, 3, and 4 are similar in size, usually number 3 is recognizably different in centromere position. The ten pairs of smaller chromosomes (none is small enough to qualify as a microchromosome) are all metacentric or submetacentric; most pairs are not individually recognizable because of similarities in size and centromere position. No heteromorphic pair of chromosomes was recognized.

Consistent secondary constrictions were not found, although "gaps" (presumably unstained bands or threads) were occasionally observed at three sites: in one cell, near the centromere on the long arm of one chromosome number 2; in four cells, near the centromere on the long arm of one chromosome number 3; in six cells, near the centromere on approximately chromosome number 9 or 10 ("gaps" appeared on both chromosomes of the pair in one cell). The last site is similar to the position of consistent secondary constrictions in some ranids with karyotypes similar to that of Cophixalus riparius (see below).

The following discussion is based on the subfamilial classification of the Microhylidae advocated by Parker (1934), except that we follow Poynton (1964) in referring Phrynomerus to the Microhylidae (subfamily Phrynomerinae) rather than to a monotypic family. Prior authors have reported examining chromosomes from a total of only eight species of microhylids, representing three subfamilies (Table 1). In addition to the karyotype described here, we present (Table 1) chromosome numbers for two more species from New Guinea, but the material is not adequate for detailed analysis.

Of the microhylids examined, the chromosomes of only three species have been prepared and illustrated in such a way that they can be compared in detail with those of Cophixalus riparius. The three species are Kaloula pulchra, Breviceps gibbosus, and Phrynomerus bifasciatus; each represents a different subfamily (Table 1). The chromosomes of C. riparius are most like those of P. bifasciatus, not only in number, but also in such details as size groups and centromere positions. Indeed, the only conspicuous difference between the karyotypes of C. riparius and P. bifasciatus is that in P. bifasciatus chromosome number 2 has a more median centromere.

Chromosome number presumably is identical (Table 1) in two species of Cophixalus (subfamily Sphenophryninae) and in an Asterophrys (undescribed species, subfamily Asterophryinae), which is consistent with the supposed close relationship of these subfamilies (Parker, 1934). Whether Cophixalus (Sphenophryninae) is more closely related to Phrynomerus (Phrynomerinae) of Africa than to Breviceps (Brevicipitinae) of Africa or to Kaloula (Microhylinae) of Asia, as might be incautiously inferred from the scanty information available, remains to be seen.

One might hope that karyotypic data could contribute evidence bearing on the problem of whether the microhylids and ranids are closely related (for example, see Kluge and Farris, 1969), or whether the microhylids are more primitive and not so closely related to the ranids (for example, see Hecht, 1963). Thus one is tempted to compare frog karyotypes at the family level, particularly inasmuch as they have been described for representatives of most families. However, the data available are too scanty to contribute meaningfully to this

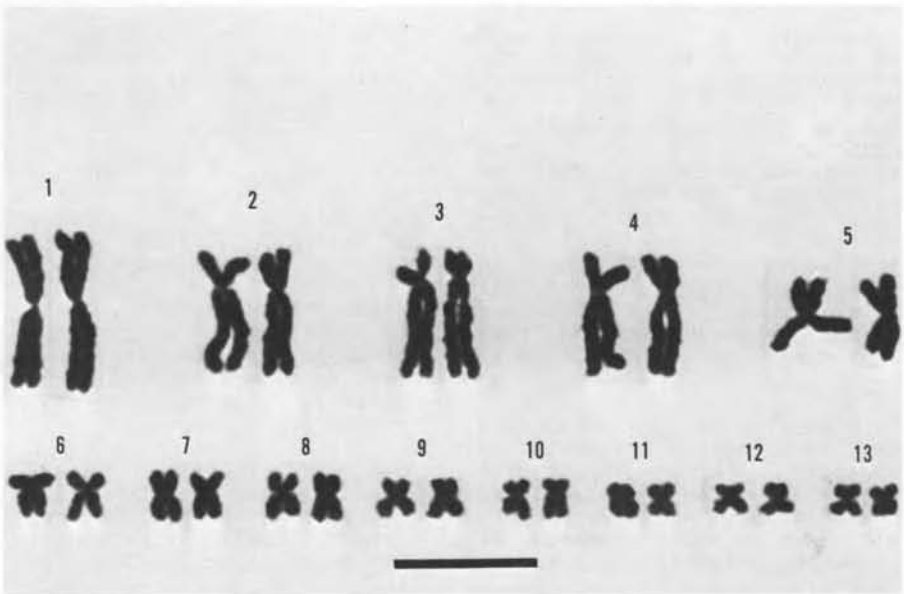

FIG. 1. Karyotype ($2n = 26$) of a female specimen of Cophixalus riparius (AMNH 82987). Line represents 10 micra.

TABLE 1. REPORTED CHROMOSOME NUMBERS IN MICROHYLID FROGS

SPECIES	SUBFAMILY	CHROMOSOMES	REFERENCE
Kaloula borealis ("Cacopoides tornieri")	Microhylinae	2n = 28, n = 14	Sato, 1936
Kaloula pulchra	Microhylinae	2n = 28	Morescalchi, 1968a, b
Uperodon systoma ("Cacopus systoma")	Microhylinae	2n = 26	Natarajan, 1953
Microhyla rubra	Microhylinae	2n = 26	Bai, 1956
Ramanella variegata	Microhylinae	2n = 26	Bai, 1956
Gastrophryne carolinensis	Microhylinae	2n = 22	Morescalchi, 1968b
Breviceps gibbosus	Brevicipitinae	2n = 24, n = 12	Morescalchi, 1968a, b
Phrynomerus bifasciatus	Phrynomerinae	2n = 26	Morescalchi, 1968a, b
Cophixalus riparius	Sphenophryninae	2n = 26	Reported here
Cophixalus cryptotympanum	Sphenophryninae	n = 13	Reported here (1); specimen AMNH 74925
Asterophrys sp.	Asterophryinae	2n = 26, n = 13	Reported here (1); specimen AMNH 74898

(1) Testicular squashes prepared by methods used by Duellman and Cole (1965).

question, and only a few observations can be made at this time.

Among the various frogs for which more or less directly comparable data on chromosome sizes and shapes are available, the chromosomes of Cophixalus riparius (and also Phrynomerus bifasciatus) closely resemble those of species belonging to three different families: Ranidae, Rhacophoridae, and Leptodactylidae. More than 15 species of ranids have been examined, and most of these have karyotypes strikingly similar to that of C. riparius (for examples, see Seto, 1965; Morescalchi, 1967; Natarajan, 1958a). Only one species of rhacophorid (Rhacophorus maculatus) has been analyzed in detail recently, and its karyotype is closely similar to that of C. riparius (see Natarajan, 1958b). The leptodactylids are more thoroughly represented by karyotypic data in the literature and show considerable chromosomal variation. At least two species (Cycloramphus asper and Oocormus microps) have karyotypes resembling that of C. riparius (see Becak, Denaro, and Becak, 1970). Other species of anurans that have the same chromosome number as Cophixalus riparius (2n = 26) have much less similar chromosome morphology and thus are not considered further here.

In conclusion, too few data are presently available to suggest likely hypotheses regarding the evolutionary significance of karyotypic similarities and differences at either subfamily or family levels.

ON THE PROBLEMS OF HOME RANGE MEASUREMENT AND INDIVIDUAL RECOGNITION IN LIZARD ECOLOGY STUDIES

William W. Milstead

During the time a recent paper of mine (Milstead, 1970) was going through the editoral process, reviewers of the manuscript touched on two problems which I think are badly in need of solution. One of these has to do with the methods by which home range sizes are measured, and the other concerns our lack of knowledge about the ability of lizards to recognize each other.

The measurement of home range size for lizards that live on relatively level land is no great problem. All that is needed are a few measurements, some graph paper, a pair of scissors, and an analytical balance. But with lizards living in three dimensional habitats (canyon walls, boulders, fence posts, trees, etc.) the problem becomes more difficult, because the amount of surface area involved undoubtedly has a direct bearing on the size of the lizard's home range. In nearly 15 years of working with the canyon lizards of western Texas, I have thought of only one method that would accurately yield information on home range size: after the boundaries of the home range have been delimited in the field, a portable paint spray apparatus could be used to spray the area with water (or water containing a vegetable dye), and under similar conditions of humidity, a known flat area such as a basketball or tennis court could be sprayed. Comparison of the volumes of water used for the two areas would yield the area of the lizard home range by ratio. I have yet to test this method because I keep hoping that someone will come up with a better or easier method.

In my paper I referred to Carpenter's (1967) statement that we have little evidence that lizards have the ability to recognize each other, and later I noted that Sceloporus merriami appears to be monogamous during the late summer with the male and female both defending the same territory. One of the reviewers raised the question of how these lizards could be monogamous without challenging their partners each time they come around a rock? The same reviewer also pointed out that the lizards seemed to be able to recognize an intruding male or female in the territory. Although these do appear to be cases of individual recognition, another possibility is that the lizards are responding to a set of very subtle signals without actual recognition. In my opinion, recognition of a set of signals is probably the best explanation for recognition of an intruding male or female, but it may not be the best explanation for the recognition between a male and female occupying the same territory. It will be of great aid to our interpretations of lizard behavior if someone can devise a study that would give evidence that a lizard can (or cannot) actually recognize its mate and other lizards living in adjacent territories.

I am grateful to Drs. Richard F. Myers and James L. Vial for critically reading the manuscript.

GEOGRAPHIC DISTRIBUTION PAGE

****

During recent years an ever-increasing number of journal editors have decided not to publish new records of geographic distribution. This decision was due in part to the feeling of some that "County Record" papers were unworthy of publication in their journals. No doubt some poorly-written papers, consisting mainly of detailed descriptions of a single specimen of some common species found 300 yards west of the previously-recorded range, were not worth the time, effort, and cost of entering them into the journal record. These decisions have been pressed also by the rapid rise in the costs of publication, with the average journal page costing $30 to $40 to print, with perhaps twice this much tied up in the reviewing and editing process.

It is for these reasons that many range extensions recently have been referred, for example, to Roger Conant for inclusion in his maps, rather than being accepted for publication.

It is our belief, however, that such new information deserves an adequate public record. We are pleased, therefore, to announce that George Zug (USNM) has offered to edit a page of such records, which can be published here at no more than $20 per page. The proposed format will provide the minimum information that is necessary for an adequate record: the species, precise locality, date of observation, disposition of specimen, and author. This will allow any interested worker to trace the origin of questioned geographic records, and to determine the data on which they are based.

Those persons who believe that some geographic record deserves more than this minimum presentation can, of course, submit it as an "Unreviewed-Unedited Communication."

Please send all geographic information for inclusion to Dr. Zug (see "Contents" page). -- HGD.

UNREVIEWED-UNEDITED COMMUNICATIONS

AN INSTANCE OF CANNIBALISM IN CROTALUS LEPIDUS (SERPENTES: CROTALIDAE)

Michael A. Williamson

Documented accounts of cannibalism among ophidians are rare in published literature. In 1955, W. J. Hamilton and Joseph A. Pollack published a stomach contents analysis study on 70 crotalid snakes from Fort Benning, Georgia. Their study revealed the ingestion of five ophidians, none of which were crotalids. Snakes accounted for approximately 8% of all ingested food items. Their study revealed no instance of cannibalism. Klauber (1956, p. 586) states "we may conclude that cannibalism among rattlesnakes in the wild is quite unusual; and, in the rare instances when it has occurred, the snake eaten has sometimes been dead before it was swallowed."

On August 11, 1962, Ted L. Brown, accompanied by the author, collected a large female Green Rock Rattlesnake (Crotalus lepidus klauberi) in Water Canyon, Magdalena Mountains, New Mexico; at an elevation of approximately 7300'. This snake later proved to be gravid. It was taken to the University of New Mexico, placed in a wooden, glass-fronted cage, and provided with a dish of water for drinking. There it gave birth to 4 young on August 29.

On November 20, one young snake ate a brood mate. Five days later it, in turn, was eaten by the adult female. A third died on November 25. The fourth member of the brood was given to the author.

This is an unusual sequence of events which may have been brought about in part by the conditions of captivity, including the artificially-enforced proximity of brood mates and their mother.

I wish to thank Dr. William G. Degenhardt for providing the records on which this note is based. I am also indebted to John S. Applegarth for reading the manuscript and offering helpful suggestions.

POISONOUS SNAKES OF THE WORLD. Bureau of Medicine and Surgery, Department of the Navy. 1968 (Reprinted 1970). A revision of the 1962 book of the same name. Completely rewritten (in 1965) by S. A. Minton, H. G. Dowling, and F. E. Russell (general editor, Comm. G. M. Moore, MSC, USN). 212 p., 120 fig., 8 col. pl. (Available from Supt. Documents, Government Printing Office, Washington, D.C. 20402. $3.25.)

CARIBBEAN RESEARCH PAGE

Many of us are aware, in a general way, that many persons and institutions have research activities in the Caribbean region: the Harvard group on anoles, Albert Schwartz on various amphibians and reptiles, a crocodile conservation project, a Virgin Islands project, and, of course, the long-standing work on sea turtles by Archie Carr's group. The work is being done by so many persons from so many institutions, however, that no one has a clear picture of the entire range of activities.

When I was recently in Jamaica, I was told that groups from Florida, Harvard, the USNM, and other institutions were either on the island -- or were expected -- or had been there in recent weeks. I was unable to get in touch with any of them, though, because no one had the details on who, where, and when.

We believe that a record of such information would be of benefit to all. Therefore, we are happy to announce that Jack McCoy (CM) has agreed to edit a page on Caribbean persons and projects -- past, present, and proposed. If you are involved, don't wait for Jack to write you, give him the information now! His address appears on the "Contents" page. -- HGD.

CONNECTICUT HERPETOLOGICAL SOCIETY

GEORGE VESPER (Vice-President, CHS) has been named Director of Roaring Brook Nature Center in Canton. DON LAWYER has taken over as Bulletin Editor. DICK PETERSON will be Public Relations Chairman. BOB DUBOS and NORM SCOTT are gathering distributional data of the amphibians and reptiles of the state.

NEW YORK HERPETOLOGICAL SOCIETY

The NYHS has announced its 1971 Photo Contest, which will be broken down into "Amateur" and "Novice" categories. Further information can be obtained from the Society, P.O. Box 3946, Grand Central Sta., NYC 10017.

H. G. Dowling (AMNH) spoke to the members on "The Crisis in Herpetological Information," on 16 January 1971.

Richard G. Zweifel (AMNH) will present an illustrated, "New Guinea: Herpetological Travelogue," on 13 February.

EASTERN SEABOARD HERPETOLOGICAL SOCIETIES

On Saturday, 17 October 1970, representatives of the PHILADELPHIA HERPETOLOGICAL SOCIETY, the NEW YORK HERPETOLOGICAL SOCIETY, the VIRGINIA HERPETOLOGICAL SOCIETY, the NORTHERN VIRGINIA HERPETOLOGICAL ASSOCIATION, and the MARYLAND HERPETOLOGICAL SOCIETY met at the Philadelphia Zoo to discuss plans for future cooperation and coordination.

A general discussion took place concerning proposed cooperation between and among the various groups, and possible joint meetings. BOB TUCK (Pres., MHS) announced that the MARYLAND H. S. would sponsor a joint meeting at the Baltimore Zoo (Druid Hill Park) on 17 December 1970. DAVE HULMS (Pres., NYHS) agreed that the N.Y. HERPETOLOGICAL SOCIETY would host a joint meeting, at either the Staten Island Zoo or the Bronx Zoo on 17 July 1971. MALVIN L. SKAROFF (Pres., PHS) announced that it was the intention of the Philadelphia group to host some joint activity during the AAAS meetings in Philadelphia (26-31 December 1971), during which the HERPETOLOGISTS' LEAGUE annual meeting will be held.

A joint meeting of officers and delegates was held 19 December 1970 in the new Hippo House of the Baltimore Zoo. The proceedings were called to order by ROBERT TUCK (Pres., MHS) shortly after 3 PM. Arthur Watson (Director of the Zoo) welcomed those present. FRANK GROVES (Head Keeper of the Reptile House) invited everyone to a tour after the meeting. Officers of other societies were then introduced. They included FRANK TOEBE (VHS), MALVIN L. SKAROFF (PHS), BARRY SCHOOR (NYHS), and FRANK WATROUS (NVHA).

Five papers were presented:

ANTHONY JANDA (Park Naturalist-Director, Brookside Nature Center, Wheaton, Md.) spoke on "The Role of the Nature Center in Environmental Education." He pointed out that most adults who come to the Center are already aware of environmental problems, and that the main emphasis must be on education of the young. They are taught as early as pre-school, and the programs work up into longer and longer programs by high school. They encourage the children to touch the specimens exhibited and to go into the field to get the feeling of being a part of nature.

GEORGE BREWSTER (nature photographer, Arlington, Va.) showed slides and played taped calls of all of the frogs and toads of Montgomery County, Maryland. He mentioned that it took two years to complete this impressive collection.

CHRISTOPHER H. DODGE (Biologist, U.S. Department of the Navy) spoke on his studies on the growth of young turtles. He reported that optima were 30 degrees (C) temperature, 24 hours light, and feeding with lean ground meat mixed with fish, bone meal, and poly-vitamins. He also reported that red-ear turtles had greater growth when centrifuged at the equivalent of 5 times normal gravity.

PETE WEMPLE (Vice-Pres., MHS) reported on the collection of the Eastern spiny softshell turtle, Trionyx s. spinifer, in Garrett County, Maryland. In company with Jeremy Jacobs, he collected some specimens on 22 September 1970. Although the species had been mentioned as having been found in the state, these are the first recorded specimens (deposited in the Natural History Society of Maryland and the USNM).

DON MORIZOT spoke on the distribution of the Long-tailed salamander within a cave in Washington County, Maryland. He investigated the location of specimens inside the cave at different seasons and found significant variation. He postulated that the animals move toward areas in the cave which are more humid.

A. JAMES BARTON (Director, Undergraduate Student Program, NSF) led a short group discussion on the effects of environmental disturbance on the survival of rare amphibians and reptiles. He is especially interested in the Bog turtle, and reiterated his plea that anyone having knowledge of the possible loss of a Bog turtle habitat because of changes in land use, or for any other reason, to forward the information to him.

The meeting ended at 6PM. There were approximately 100 people present, who were all well-pleased with the program.

RENE KATZ-BRAUNSCHWEIG (Advisor, NYHS) reminded all present of the joint meeting in New York on 17 July 1971. MALVIN L. SKAROFF (Pres., PHS) reiterated his welcome to attend the joint meeting at the Philadelphia AAAS meetings, in conjunction with the HERPETOLOGISTS' LEAGUE.

MARYLAND HERPETOLOGICAL SOCIETY

BOB TUCK (President) writes: "You will find us in the forefront of the battle to save the environment. We make no pretentions of being professionals, but we do represent a considerable force at the professionals' disposal." The Society heeded Bustard & Limpus' plea for the Flatback sea turtle, Chelonia depressa (HERPETOLOGICA 25(1): 29-34) and registered a protest to the Woongarra Shire

Council, Commonwealth of Australia, on the proposed subdivision and land development adjacent to the turtle's nesting site. It also publicly praised the action of the City of Bowie, Maryland, in passing the nation's first city ordinance banning the sale of soft drinks and beer in non-returnable containers, and "we alerted the Eastern Seaboard Herpetological Societies to this history-making development."

Some of the 1971 activities include:

20 Feb. STANTON ERNST, JR. (Gulf Nature Center, Arlington, Va.) "The role of the Nature Center in Herpetological Education."

20 Mar. PETER MUNDEL (Dept. Zool., Univ. Md.) "The ontogeny of photoxic responses in the Red-spotted newt, Notophthalmus v. viridescens."

17 Jul. Second Combined Meeting, ECHS, New York. Hosted by NYHS.

16 Oct. The Honorable Lawrence J. Hogen (Fifth District, Md., U.S. House of Representatives), "Legislative aspects of conservation and wildlife protection."

28 Dec. Third Combined Meeting, ECHS, Philadelphia, Hosted by PHS.

INDIVIDUALS

AND

INSTITUTIONS

****

RICHARD J. BALDAUF (Texas A & M) was appointed Chairman, Texas Academy of Science Conservation Committee.

ERNEST C. TANZER (U Ariz) received a SIGMA XI grant toward his study of the functional anatomy of the jaw apparatus of Agkistrodon, Crotalus, and Sistrurus.

KENNETH L. WILLIAMS (NW St. U, La) has completed his studies of the taxonomy of Lampropeltis triangulum.

BILL THORNTON (Angelo St U, Texas) received a Faculty grant toward his biochemical and cytological study of the genus Tantilla.

JAMES SCHWARZ (McLennan Comm Coll) had his NSF grant extended for his studies of head-bob patterns in Sceloporus poinsetti.

SHERMAN & MADGE MINTON have started another book -- this time on "Giant Reptiles."

WARREN WALKER (Oberlin) has returned from a year's work at the Anatomical Institute (Frankfurt), where he was able to complete some papers on limb musculature and locomotion in turtles.

ERNEST E. WILLIAMS (MCZ) recently was appointed Professor of Biology, in addition to his curatorship.

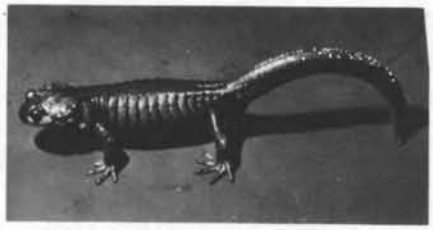
AFRICAN BIBLIOGRAPHY (1860-1960)

****



A bibliography of African herpetology was prepared by Arthur Loveridge (MCZ) and updated to 1960 by Raymond Laurent. The Museum of Comparative Zoology was unable to obtain funds (e.g., from NSF) for its publication and has given the manuscript to HISS. The MS consists of some 581 pages, of which 52 are introductory material (mostly journal abbreviations). Although it will be some time before we are able to incorporate these titles into our computerized bibliography, we will try to aid anyone who needs bibliographic aid on African herpetology.

****

Trionyx hurum Gray, the little-known Burmese soft-shelled turtle, retains a juvenile pattern of well-defined ocelli. Similar markings are seen on young specimens of related Asian Trionyx and Dogania, hatchlings of some emydid turtles, and even Chelys fimbriatus, which belongs to another suborder. The value of this coloration -- often considered as aposematic -- is puzzling in such an old type of reptile, which reentered water during its evolution. In addition, T. hurum spends much of its time under mud, as do the related American species.

The turtle in the photograph is a juvenile specimen, carapace length 123 mm, width 96 mm, weight 193 g; in captivity 1 1/2 years. -- W. Sachsee (Ricarda Huch Str. 6, 65 Mainz, Germany).

Defensive behavior of the salamander, Ambystoma gracile. The tail and head are lashed against the predator. The white globules on the skin are noxious secretions from the granular glands. -- Edmund D. Brodie, Jr. (Zoology, Clemson U., Clemson, S.C. 29631).

STULL'S "BOIDAE"

****

Unknown to most workers, Olive Griffeth Stull continued her work on the systematics of boid snakes until a short time before her death, and left an almost-complete manuscript. This MS is now in HISS's files. It consists of several hundred typed (but unnumbered) pages of systematic accounts of the genera and species of boids, drawings of color patterns and (inverted and split) hemipenes, tables of scale counts and measurements, and outline maps for both genera and species. Lacking are an introduction, key, and familial summary.

The overall format of the accounts is like those in her Pituophis (1940, BULL U S NAT MUS (175)) paper. None of the sections appears to be ready for publication, but anyone who is working on boid taxonomy should know of the existence of this work. We will try to make appropriate parts available to those workers who need them.

PERMITS FOR SCIENTIFIC EXPEDITIONS TO BRAZIL

****

Following is an English translation of the Brazilian Congressional Decree approving the regulations for permission to conduct scientific expeditions in Brazil. This information was made available to William E. Duellman by Dr. Bertha Lutz and Dr. Antonio Moreira Couceiro, Presidente, Conselho Nacional de Pesquisas. Information concerning, and applications for, permits should be addressed to: Presidente, Conselho Nacional de Pesquisas, Av. Marechal Camara 350, Rio de Janeiro, GB. ZC. 39, Brazil.

Decree No. 65.057 -- of August 26, 1969

Art. 1 - The supervision of Scientific Expeditions in Brazil, entrusted to the National Research Council of Brazil under Decree no. 62.203, of January 31, 1968, shall be governed by the terms of the present Decree.

Art. 2 - For the purposes of the present Decree, a Scientific expedition shall be considered as the displacement of human and material resources to a given geographic area, for a limited period of time, with a view to developing a specific plan to obtain scientific data and knowledge, to confirm or establish theories, thus endowing it with a broader scope than that of simple research to evaluate natural resources.

Art. 3 - The present Decree shall not apply to: a) activities governed by Decree no. 63.164, of August 26, 1968, when carried out on the continental shelf, on territorial ocean waters and on interior waterways; b) research lying within the monopoly rights of the Union or within the competence of other Agencies and Ministries, governed by specific regulation.

Art. 4 - It is the duty of the National Research Council, excepting in the aforesaid restricted cases, to authorize and to supervise scientific expeditions or any other activities involving the exploration, survey, collecting, filming or recording of scientific material effected by: a) foreign institutions or individuals, in an official or private capacity; b) foreign religious or philanthropic associations, established in the country; c) Brazilian institutions working in collaboration with foreign institutions or individuals; d) national private institutions or individuals. [Authorization under letters a, b, and c, as well as under letter d, shall be previously submitted to the National Security Council, whenever the expedition areas concerned be considered vital to National Security, or the research involved be considered of interest to National Security.]

Art. 5 - Any Government official who ascertains that foreign members of expeditions cleared under the terms of the present Decree are carrying out activities contrary to the national interest, or effecting research legally classified as within the Union Monopoly, shall inform the Ministry of Justice thereof, so that a legal suit for expulsion may be filed, in accordance with official legislation in force.

Art. 6 - It is the duty of the National Research Council of Brazil, under the terms of Decree no. 62.203, of January 31, 1968: a) to study the aims of scientific expeditions and correlated activities, from the angle of their interest to national research; b) to decide as

to the integrity and merits of organizations or individuals wishing to carry out scientific expeditions or correlated activities, and as to the convenience, from the point of view of national interest, of granting the permit requested; c) to study, with the assistance of the relevant agencies whenever necessary, the aims, routes and plans presented; d) to inform the relevant authorities of the decision on the application for permits; e) to supervise, directly or by delegation, the activities authorized; f) to appoint delegates in the States and Territories, when the supervision cannot be effected under the terms of letter e; g) to appoint its representatives to accompany the expeditions governed by article 4; h) to withdraw the permit granted, whenever there be a breech of the regulations under this Decree; i) to state its opinion and to request that of the Ministries, should the matter be within their jurisdiction, on the exportation of any specific material collected within the national territory; j) to advise, and exchange information with, the relevant Ministries and official agencies on the results obtained by scientific expeditions.

Art. 7 - Applications for permit shall be addressed: a) directly to the National Research Council, when the expedition or activity be proposed by a national organization or individual, by a foreign religious or philanthropic association established in the country, three months before the date for starting the operation; b) to the Ministry of Foreign Relations, through diplomatic channels, when the expedition or activity be proposed by a foreign organization or individual, 180 days before the date set for arrival in Brazil.

Art. 8 - Applications for permit to carry out expeditions and other scientific activities, shall contain: a) a detailed and precise statement of the purposes thereof; b) name, address, nationality and reports on previous activities in the national territory, if any, of the organization or individual responsible for the financial support of the activities proposed; c) name, address, nationality and reports on previous activities, in the national territory, if any, of the organization or individual responsible for the carrying out of the activities proposed; d) name, "curriculum vitae" and nationality of the person in Brazil responsible for the activities and of the person designated to act for him in any possible absence; e) name, address and nationality of the participants; f) routes and plans; g) type of material to be collected and destination thereof; h) detailed inventory of equipment and arms to be carried; i) duration of the expedition; j) specification of the customs station, chosen from among those listed by the Council, through which the material collected will be exported; k) formal statement of intention to abide by the laws in force in this country and by the provisions of this Decree.

Art. 9 - All the information demanded in the previous article together with the decision of the National Research Council thereon shall be included in the documents to be submitted to the authorities mentioned in article 4, for appropriate scrutiny.

Art. 10 - In order to obtain extension of a license period, the interested parties shall apply to the National Research Council to that effect thirty days before the existing license expires, stating the reasons for their request and presenting a report on the work already carried out. [The procedure for extention of the license period shall be the same as that for obtaining the initial permit.]

Art. 11 - The supervision of authorized activities shall be effected by the National Research Council, within the provisions under article 6: items e and f.

ss. 1. - Any material held by expeditions or participants thereof, collectors or researchers, in disagreement with the provision in the present Decree, or with the limitations established in the license involved, shall be confiscated.

ss. 2. - The material thus seized shall be handed over to an official scientific institution of the National Research Council's choice.

Art. 12 - The exportation of any collected, filmed or recorded material shall depend on the presentation to Customs, port of embarcation or post-office officials of the respective authorization given by the competent Ministry or Agency, based on the scientific pronouncement thereon of the National Research Council. [The exportation of any mineral or fossil material collected within the national boundaries shall be controlled by the Ministry of Mines and Energy, in accordance with the legislation in force thereon.]

Art. 13 - Prior to the granting of authorization, an appraisal and inventory of the material collected in the national territory shall be made, and the specimens to remain in the country, or to be returned in the course of time, to be added to collections of Brazilian official institutions, shall be specified. [The interested parties shall have the right to attend the examination of the material, either personally or through their representatives.]

Art. 14 - Holotypes shall be kept in Brazilian official institutions.

Art. 15 - For the purpose of being added to the collection of a national institution named by the National Research Council the following material shall be delivered to the latter: a) representative samples or duplicates of collections obtained; b) moulds, copies, photocopies or drawings of scientific material.

Art. 16 - The National Research Council, taking into consideration scientific ethics as well as the cultural interests of Brazil, shall determine, in each and every case, the ultimate destination to be given to unique or rare specimens.

Art. 17 - In the case of retention of material in Brazil, the National Research Council may entrust an official institution to decide, in cooperation with those responsible for its collection, on the destination of the same.

Art. 18 - The leaders of the scientific expeditions or correlated activities duly licensed, within 6 months of their departure from this country shall send the National Research Council a detailed report on their work in Brazil.

Art. 19 - The present Decree shall be in force as of the date of its publication, all provisions to the contrary being hereby repealed.

BOOK REVIEW

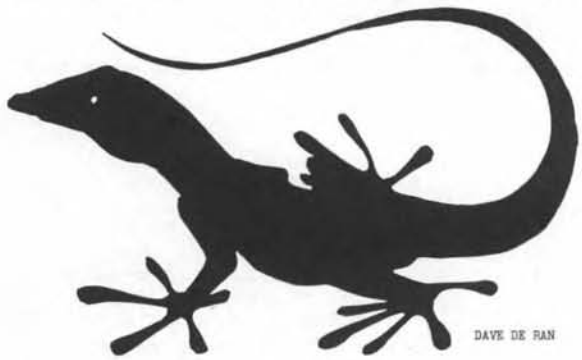
****

REPTILES OF OKLAHOMA. By Robert G. Webb. 1970. Stovall Museum of Science and History, University of Oklahoma, Norman. xi + 370 p., 120 figs. $3.95, paperback; $8.95 cloth.

"Long awaited" is an overworked part of the reviewer's lexicon, but the cliche has become reality with the appearance of Webb's REPTILES OF OKLAHOMA. This book had its origin in keys published by A. I. Ortenburger in the early 1930's, and in a dissertation prepared by Webb in 1952. Despite the lengthy delay in getting this work into print, it has been worth the wait. This is one of the best state reptile books available.

Webb recognizes 95 species and subspecies of reptiles in Oklahoma, and discusses another half-dozen "unverified, problematical, and probable species." Keys to orders, suborders and species are well-constructed, free from excessive detail, and easy to use. Scale terminology and diagnostic structures are illustrated by line drawings taken from various sources. Some of the illustrations would have been improved by selective cropping of unnecessary parts. Eleven species are polytypic in Oklahoma, and their subspecies are diagnosed in the species accounts.

Each of the 80 species accounts includes a succinct descriptive paragraph, intended to be used as an aid to identification, and a general statement of range in the state. Exhaustive lists of specimens examined, museum records, and literature records document the statement of range. A clear, full-page spot map is provided for most species, but these would have been greatly enhanced by the addition of inset maps showing total range. The well-spotted maps attest to the author's thorough approach to distributional data.



The species accounts also include bibliographic citations to the Oklahoma literature and quite a few original observations on habitat, feeding, reproduction and behavior of Oklahoma reptiles. Webb has analyzed carefully most problems of geographic variation in the state, and his discussions of these situations are models of clarity. Reviews of unsolved taxonomic and zoogeographic problems outline avenues for further investigations. In the few cases where data are incomplete, such as in Natrix erythrogaster flavigaster and Coluber constrictor priapus, the author frankly admits the limitations of his treatment.

The keys and species accounts form the backbone of this book, but it contains much more. A well-documented account of faunal regions, illustrated by photographs and maps, does remarkable justice to the great ecological diversity of Oklahoma. Faunal relationships of the reptiles are outlined in a skimpy chapter, but this subject could easily fill another 300 pages if treated incautiously. Oklahoma localities, confusing at best and frequently impossible, are discussed in another well-polished chapter. Several maps depict boundaries of the ameboid political units of pre-statehood days. Two of the best sections, both basically historical in content, treat previous herpetological work and type-specimens and type localities of reptiles in Oklahoma. A glossary, twenty-two pages of bibliography, and an index complete the volume.

In short, there is something here for everyone. There are solid raw data for the zoogeographer and systematist, good research leads for the advanced student, and usable identification aids for the novice. There is even a color painting of Crotaphytus collaris to delight George Miksch Sutton fans. This book is a sound contribution that effectively combines the utility of a handbook with the value of basic data. I recommend it as a worthwhile addition to any herpetological library.

BOOK REVIEW

****

ANIMAL ELECTROENCEPHALOGRAPHY. By W. R. Klemm. 1969. Academic Press, New York. xii + 292 pp., 156 figs.

This relatively compact reference book is written with enough technical detail to provide a diverse group of readers with important general information and a rapid introduction to selected topics in EEG. A wider application of EEG techniques can be expected in the future. While the book strives to provide a theoretical framework which will enable the investigator to understand what he does, it also provides a useful tool to help him to communicate his findings to others. In Appendix A (p. 269-276) a "Proposal for an EEG Terminology by the Terminology Committee of the International Federation for Electroencephalography and Clinical Neurophysiology" is provided (reprinted from Electroenceph. Clin. Neurophysiol. 20: 293-320) with a glossary and equivalent terms in English, French, German, Italian and Spanish.

The 34 pages of references, author and subject indexes and the 156 figures enable readers with diverse objectives and academic backgrounds, to gain sophisticated understanding in selected topics of EEG.

A FURTHER REPORT ON GALAPAGOS TORTOISES

Peter C. H. Pritchard

Following Herndon Dowling's broad hint in the recent issue of Herpetological Review, I am happy to present this report of my trip to the Galapagos Islands early in 1970. My basic mission in the islands was to carry out a preliminary survey of the sea turtle populations that nest there. However, having a long-standing interest in giant tortoises, I was keen to visit as many of the tortoise populations as time and boat availability permitted. Only on James Island did we take a guide, yet we found tortoises with no trouble at all on all four islands where we looked for them. In fact, I was very happily surprised by how evident the native Galapagos fauna was, although it is true that we also came across many goats on James and northern Indefatigable, donkeys on James and Albemarle, and pigs on James and southeast Indefatigable. The oft-mentioned rats of Duncan Island, which are thought to have prevented the native tortoise race from reproducing successfully for seventy years, appeared to be at a very low ebb; I saw no live rats and only one old, bleached rat jawbone. Probably the prolonged drought had caused a massive population drop in the rodents, though the native reptiles of the island, well adapted to arid conditions, appeared to be doing well. The endemic lava lizard, Tropidurus duncanensis, was very abundant in the higher parts of the island.

Van Denburgh found no tortoises anywhere at the western end of James in 1906, but even today it is possible to find tortoises within about an hour's walk of James Bay. One old female tortoise has been imprisoned in a steep-walled crater at the southern end of the Bay for many years. the floor of the crater is about 600 yards in diameter, and is mostly covered with low bushes. I climbed into the crater on February 6 and eventually found the old tortoise under the very last bush in the whole crater. It seemed to be in good health though was fairly light for its size, probably being somewhat dehydrated; the only standing water in the crater was saturated brine, and the air was exceedingly hot and still. However the tortoise and the numerous goats in the crater seem to be able to extract sufficient water for survival from the vegetation.

James Island is usually described as lacking human inhabitants. However, for the last five years one man, an Ecuadorian named Leonardo Apolo, has lived at James Bay, caretaker of an abandoned and bankrupt salt mine. He knew where we could find more tortoises on James, and on February 10 we set out together to find them. We drove by tractor to the salt mine, about half a mile inland, then struck out into the interior on foot. Before long we came across tortoise droppings (consisting mainly of barely-digested manzanilla), and within an hour and ten minutes of setting out we found a large male tortoise resting under a bush. Another male was only a few yards away; when we found it, it was eating large numbers of manzanillas, but soon it walked over to the first tortoise and started biting at its legs. In the general vicinity we found two more tortoises - these too were both adult males; and in a crevice I found the complete skeleton of an adult female. This tortoise had been blind in one eye, since the skull was asymmetrical and there was no space for the left orbit. This deformity was presumably the reason for its fatal fall.

Tortoises are still quite plentiful in the southwestern part of Indefatigable Island, and this area has been designated a tortoise reserve. This, of course, does not imply that those tortoises which are found wandering outside the reserve may be taken, but it does mean that the land within the reserve is not available for settlement or agriculture. I made the five-hour hike inland to the tortoise reserve on February 26, and was able to see several dozen tortoises in the vicinity of the "caseta," a small hut inhabited by two wardens. However, this time of the year was exceedingly dry, so there was no standing water, and the tortoises were widely dispersed. There are no good trails within the reserve, and although much of the country is easy walking, it is very easy to get lost; I found it advisable to take a canteen of water even on a very short walk. The Indefatigable tortoises are breeding quite well; the feral hogs, which eat tortoise eggs and hatchlings whenever they find them, are shot on sight, and are now considerably reduced in number. Whenever a tortoise nest is found by the National Park officials or by the game wardens, it is surrounded by heavy stones so that hogs cannot force an entry, and the young tortoises are released in thick vegetation. The hatchlings and young have a strong instinct to flee from bright light, so they remain

FIG. 1. Large male G. e. vandenburghi following a "tortoise trail" inside Volcan Alcedo, Albemarle Island.

well hidden and adequate numbers survive. In fact, the population is sufficiently dynamic for well over half of the tortoises to be small enough to be picked up by one man, though the occasional old male reaches perhaps 500 lbs.

Tortoises still exist on all five of the principal volcanoes of Albemarle Island, though the populations on the southern two mountains (subspecies elephantopus and guntheri) are down to a few hundred each; in former years they were heavily exploited by settlers, and now they are seriously harassed by feral dogs, cats, hogs, and other introduced mammals. The northern two populations (becki and microphyes) are reported to be in fairly good shape, and breeding; there is no human settlement on the northern part of Albemarle, and most feral mammals are confined to the south. A notable exception to this is the donkey, but fortunately this appears to be about the least harmful of the introduced mammals. However, there is always the danger of their trampling young tortoises or destroying nests by rolling on them, and ultimately it will be necessary to eliminate them.

The one place in the Galapagos where tortoises may still be seen in primordial abundance is on the central volcano of Albemarle, known as Cowley Mountain or Volcan Alcedo. There is no good landing place at the foot of Alcedo, so the crews of the old whaling vessels obtained their tortoise supplies elsewhere, and although Van Denburgh found an abandoned tortoise slaughter encampment on the mountain in 1906, apparently no one got into the actual crater until only a few years ago. The walk from the shore to the rim of the crater is exhausting and takes about twelve hours, but the substrate for most of the trip is soft pumice, and is the easiest walking terrain in the islands. I spent February 17 and 18 on Alcedo, camping the night on the rim of the crater. The terrain for a few miles inshore is very barren, even Tropidurus lizards being very scarce, and tortoises are not found until one has walked inland for some hours; in fact we had only found three tortoises, and they all small, by the time we reached the crater rim. But by walking round the rim itself, towards a steaming geyser which we could see half way down the opposite side, we found several dozen. There were also twenty or so tortoises sitting in a muddy pool into which the geyser had overflowed, and on the slope down to the crater floor, and on the floor itself, tortoises were continually to be seen on all sides. We must have seen 400 in one morning. About half of the tortoises were less than two feet long, while the smallest was only five inches, but the adult males were enormous, bigger than any I have seen in captivity. One monster measured 51 inches in a straight line (69 inches over the curve), and many were nearly that big. I saw two attempts at copulation - one prolonged and apparently successful, but in the other case the male had mounted the female from the wrong end. Otherwise the tortoises were either eating whatever vegetation was within reach, or walking along the amazing complex of trails they had engineered on the inner slope of the crater. On the floor of the crater a broad promenade which could only be called a tortoise super-highway stretched for hundreds of yards. We saw numerous donkeys inside and outside the crater. We also saw quite a number of donkey skeletons, but despite the great number of living tortoises we saw all around, we did not see a single dead tortoise or even an old skeleton.

FIG. 2. Male and two female Duncan tortoises (G. elephantopus ephippium) in their native habitat. The Pacific Ocean is in the background.

The only other tortoise population I visited was that on Duncan Island. It is amazing that this population has survived at all. Reproduction of the Duncan race has been virtually nil since the beginning of this century, when rats were introduced to the island. The island is very small (about three miles in diameter), and the tortoises have been subject to heavy collecting, not only by the old buccaneers and whalers, but also in the present century by scientific and quasi-scientific parties. Van Denburgh collected 86 tortoises from the island in 1905-1096, and up to about 1960, no Galapagos expedition was considered complete unless one or two Duncan tortoises had been collected. Nevertheless, it is estimated that about 100-150 tortoises still survive on Duncan, all of them very old.

I ascended Duncan from the south-west on February 25. After only about an hour's walk, I saw a tortoise on the trail ahead of me. It had its head high in the air and looked more like a small giraffe than a tortoise; however, when approached, it shyly withdrew its head and looked like a tortoise again. I wandered around in the area for a few hours, and found seven tortoises altogether - three males and four females. During the middle of the day, all were hiding under overhanging rocks or natural rocky cairns to escape the extreme heat. Despite the heat and the complete lack of standing water, one tortoise which I picked up squirted a considerable volume of limpid water from its bladder. I felt sorry to have made this tortoise relinquish its emergency water supply, and did not pick up any others.

The rats on Duncan Island consume practically every baby tortoise soon after it hatches (though Tjitte DeVries did recently find one yearling on Duncan which had been attracted by the banana in a trap he had put out to catch rats). However, during the last five years, a magnificant conservation program has been carried out which has changed the Duncan tortoise's prospects from very gloomy to very good.

Once a nest of eggs is located, it is marked and left *in situ* for several months. The eggs are then carefully removed and taken to an incubator at the Darwin Station, where an incredible 85% produce viable hatchlings. Over 100 young have now been hatched at the Station, and these are raised for five years before being released on Duncan at a presumably rat-proof size. The first release was due to take place shortly after I left the islands in March. The young are fed only on leaves, and so only reach a length of about one foot during these five years. It would probably be possible to increase the growth rate by feeding them on a synthetic diet, but many reptile keepers have found that reptiles which grow unnaturally fast tend to die suddenly; as it is, the post hatchling mortality of the captive Duncan tortoises is very low. Captive-raised hatchlings in San Diego reach a size of about one foot after three years or less, but they are of subspecies which have a much greater adult size.

As far as the other island populations are concerned, the Chatham Island population, which includes young specimens, was rediscovered several years ago on a remote part of the island, having previously been thought to be extinct. Now over 100 individuals have been marked. The Hood race is extremely rare, only seven individuals having been located (two males and five females). One male and three females have been transferred to a large enclosure near the Darwin Station, where mating takes place frequently. The latest word is that, during July this year, three nests were made, containing a total of 18 eggs, so it is possible that the Hood tortoise can yet be rescued from the very brink of extinction. Certainly there should be time to experiment with different breeding conditions, since the four Hood tortoises at the Station are all in their prime, judging by their well-marked growth rings, and since under the excellent conditions the Station provides, there has not yet been a single death among captive adults of any race.

The problematical Narborough Island tortoise has still not been seen since Beck's single specimen was collected in 1906. The island is free of human settlement and feral mammals, yet a party of highly experienced tortoise men were unable to find even traces of tortoises on Narborough in February this year, though John Hendrickson found a piece of tortoise dung and some cactus pads with tortoise-like bite marks in 1964. Narborough is a still-active volcano, and the area where Beck collected his tortoise is now covered with fresh lava. The general feeling is that there must be one or two left on Narborough somewhere, but no one seems able to find them.

The Abingdon Island tortoise has also eluded recent attempts to locate specimens, and it is possible that it is now extinct. Tortoises on this island were heavily collected by whalers, but no mammals were introduced until 1958, when a settler illegally brought in three goats. These have now increased to thousands, and are systematically clearing off the vegetation of the island. One theory is that the tortoises were forced to seek food in unaccustomed parts of the island and were all killed by falling into crevices. Certainly shells and bones apparently only a few years old may be seen in crevices on the island; but it would be sad indeed if the last individuals had already gone this way. The island is rarely visited, and one or two survivors may remain.

The tortoises of Barrington and Charles Islands were wiped out a long time ago. I do not believe that the population race attributed to Jervis Island has any real existence. The type of *Testudo wallacei* (the supposed Jervis race) is in fact of unknown origin, and the single tortoise definitely collected on Jervis (by Beck in 1905) had the appearance of an Albemarle tortoise, and had probably been introduced from that island by Georg Baur. Jervis is too small an island for a population of viable size to have eluded discovery.

As Herndon Dowling has mentioned, it is very sad that Miguel Castro found conditions too intolerable to continue his work in Galapagos. But it would be wrong to give the impression that conservation in the islands is not now in good hands. Two resident Ecuadorian National Park officials, Sr. Black and Sr. Villa, have been carrying out able and vigorous work on the tortoises of all the islands. The Duncan tortoise program continues, fertile eggs have now been collected on Chatham Island and brought to the station for incubation and raising of the young, and soon we may have the first hatchlings of *hoodensis*. Nests are being protected on James and Indefatigable, and predator control on South Albemarle is being carried out. Also, education of the local people into the significance of the Galapagos fauna is being undertaken; this is the only way to prevent recurrences of events such as the tragic introduction of goats to Abingdon only a few years ago. Galapagos conservation is now in the hands of a multi-national band of uncommonly tough and dedicated men - Black and Villa, mentioned above; Roger Perry, the Director of the Darwin Station; Tjitte DeVries, the resident ecologist; Daniel Weber, and Craig MacFarland, a graduate student from the United States who is doing an in-depth ecological study of the Indefatigable tortoises, with comparative observations on tortoises of all the other surviving populations. Moreover, the old problem of transportation should have been solved by the arrival of Beagle III, a boat fast enough to reach any point in the islands within twelve hours.

FIG. 3. Male Duncan tortoise, showing high, wide front of shell.

[It seems only appropriate to point out: 1) the forementioned tortoise colonies were all mapped and marked by Castro; 2) the two park rangers, though appointed by the Ecuadorian government, had their salaries paid by Lars-Eric Lindblad (Lindblad Travel); 3) Roger Perry is no longer director of the Darwin Station, and no new director was appointed for more than six months after he left; and 4) Beagle III still has not arrived (Beagle II sank in September, 1968). -- HGD]

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be typewritten on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $16.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/4 inches (one column) or 9 3/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 13 1/2 inches). Line cuts are reduced 25 per cent in processing.

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

UNREVIEWED-UNEDITED COMMUNICATIONS

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions (see Advice to Authors).

Page charges are: $20 for a single page (158 lines of about 45 characters and spaces); $40 for the two-page maximum (320 lines). Include an allowance for the title and author's name and five lines for the address and received date. [Send a check for the proper amount with the manuscript, or if you prefer, we will bill you that amount for reprints.]

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, due largely to the originality and diversity of its publications program, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

Purpose. The SSAR encourages the acquisition of knowledge on amphibians and reptiles and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communication between amateur and professional herpetologists, so that they may work together in the common cause of furthering science.

Publications. The Society publishes the JOURNAL OF HERPETOLOGY, FACSIMILE REPRINTS IN HERPETOLOGY, and HERPETOLOGICAL REVIEW. Members receive all regular issues of these publications.

Membership & Subscriptions. Membership is open to anyone interested in amphibians and reptiles. Regular dues for 1971 are $8. in the United States and Canada, $6. in other countries; Sustaining dues are $10., Contributing $15., and Life $100. Subscriptions for institutions and individuals are $16. All inquiries about membership or subscriptions should be addressed to the Secretary.

****

EDITORIAL

****

As an indication of our interest in the field of herpetology, not merely of SSAR, we carry in this issue the program and abstracts of papers for the Chicago meeting of the HERPETOLOGISTS' LEAGUE. This is the first time that abstracts have been published for HL meetings.

Economic pressures as well as those of common interest are serving to emphasize the need of a single society of herpetology. Dues in both SSAR and HL will rise to $8. in 1971. Only by pooling their finances and memberships will such societies, with much the same interests, be able to survive. Thus, may we all hope that the proposed meeting of SSAR and HL boards of directors lead to an early move toward unification.

On another subject, HISS was selected as the depository for SSAR archives, with the expressed hope that it would become the depository for all herpetological societies and herpetologists. HISS will perform this responsibility to the limits of its facilities and storage. -- HGD.

NEW YORK'S "MASON ACT" UPHELD BY COURT

An act passed by the New York Legislature (Agriculture & Markets Law, Section 358-a, 3 February 1970) which prohibits the importation or sale of animals or their skins which are "deemed to be near extinction" has been validated by the State Court of Appeals (15 October 1970). Specifically included under the prohibition are "alligators, caimans, and crocodiles."

The law had been challenged by several shoe and leather-products companies on the basis that the state law included animals that were not considered endangered in the recently-enacted Federal "Endangered Species Act" (Public Law 91-135, 5 December 1969), and thus exceeded State authority. This contention was upheld by a lower court, but the Court of Appeals held that the Legislature had the right to extend coverage to any species which it considered to be subjects of exploitation, and thus threatened.

Both of these laws were preceded by the "Low Bill" (New York City Council No. 943-1124, 14 March 1969), which prohibited the sale of American alligator products in the City. Together, they appear to offer full protection to crocodilians in this state -- a major style, manufacturing, and sales center for "alligator" products. However, Paris, Rome, and Tokyo are also large producers of fine leather, and we must wait and see if they will prohibit crocodilian products before their sources disappear. If no steps are taken, it is likely that most crocodilian species will be extinct before the end of the decade. -- HGD.

NEW AFRICAN CONSERVATION CONVENTION

The new African Convention for Conservation of Nature and Natural Resources, signed in Algiers by 38 Heads of State or their representatives in September, 1968, is now in effect. Among the "totally protected" animals are two toads (Bufo superciliaris, Nectophrynoides), all marine turtles, the Giant, Angulated, and Radiated tortoises, the boas Bolyeria, Casarea, and Acranthophis, and two lizards, Uroplates and Macroscincus. Crocodiles also are "totally protected" but may be hunted under special permit in some countries. (Listings and a history of the Convention are given by Kai Curry-Lindahl in ORYX 10(2): 116.)

NEXT ISSUE

A report on the Galapagos tortoises by Peter C.H. Pritchard, who spent some weeks on the islands, will appear in the February issue of HERPETOLOGICAL REVIEW.

LETTERS

ON THE FUTURE OF THE GALAPAGOS TORTOISES. -- We have been very dismayed by a recent article in Herpetological Review (2(2): 3, 1970) pertaining to the plight of the Galapagos tortoises. It seems apparent to us that this is the last opportunity to initiate any sort of conservation effort to save these animals. It is most disturbing to note that no concerted conservation program is currently underway.

We are of the opinion that the Darwin Foundation conservation program does not (and probably never did) meet the minimum standards necessary for success, and that its shortcomings have been accentuated by Mr. Miguel Castro's leaving. The stakes are too high to expect one man or one organization to bear full administrative responsibility. We feel that the biota of the Galapagos is so unique and important that a joint conservation effort on the part of many organizations would be a minimal request. A trust fund could be established through the pooled allocation of funds by the National Science Foundation, World Wildlife Fund, National Wildlife Federation, the Audubon Society, International Turtle and Tortoise Society, Society for the Study of Amphibians and Reptiles, etc. The problem enters the domain of all the above, as what is really at stake here is an entire biota, not solely a herpetofauna.

The fund, supplemented by donations, could be established as an investment, the proceeds of which would go towards maintaining the Islands in cooperation with the Ecuadorian Government. To be effective, the program would have to consist of: 1- enough wardens to patrol shorelines (by outboard motor boat) and prevent fishermen from taking tortoises, ruining habitat, etc.; 2- systematic eradication of feral pigs, rats, goats and dogs; 3- propagation of tortoises by retrieving and hatching eggs in enclosures, along with restocking. This program is of such grand scale that we do not feel it to be within the funding capabilities of any one organization. Only in a joint program could the financial burden be met.

Time runs short, and the forces presently at work destroying the remaining tortoise populations will not stand in abeyance while we try to reach a decision as to what course of action should be taken. We recommend that the officers of major conservation groups communicate with each other and take immediate steps toward planning and initiating a suitable conservation program.

The HERPETOLOGISTS' LEAGUE is an international organization of professional and amateur herpetologists dedicated to furthering knowledge of the biology of amphibians and reptiles. It was established in 1936 by Major Chapman Grant. In 1969 it had 937 members and fellows, and 491 institutional subscriptions to its journal, HERPETOLOGICA, in the United States and 38 foreign countries.

Anyone with an interest in herpetology is eligible for membership. Members receive HERPETOLOGICA, to which they can submit manuscripts for publication, and may present papers at the annual meeting, which usually is held in conjunction with the AAAS meetings. However, the "Members" class does not hold voting rights in the League.

The business of the League is handled by the Officers, who are the President, Vice-President, Secretary-Treasurer, Editor-in-Chief, and the Executive Council. The Council is made up of the last three Presidents and six Fellows three of whom, are elected (biennially) for four-year terms. The Secretary-Treasurer and the Editor-in-Chief are appointed; other officers are elected by the Fellows.

The President of HL is Wilmer W. Tanner (Brigham Young U), the Vice-President is T. Paul Maslin (U Colorado), and the /acting/ Editor-in-Chief is Ronald Altig (Mississippi State U). Council members include K.S. Norris, P.W. Smith, J.M. Legler, J.R. Dixon, V.H. Hutchison, S.A. Minton, R.G. Zweifel, D.B. Wake, and C.J. McCoy.

The "Fellows" class holds voting rights in the League. Fellows are elected annually by the Executive Council "on the basis of their contribution to the science of herpetology," upon being nominated by a Fellow or an Honorary Member.

Like other societies, the HERPETOLOGISTS' LEAGUE has found it necessary to raise its dues recently. Dues and subscriptions for 1971 will be:

Members..... $8.00
Fellows..... 10.00
Institutions... 15.00

/The information presented above was abstracted from notices in HERPETOLOGICA, the League's Constitution, and recent information from the President and the Secretary-Treasurer./

28-29 DECEMBER

PROGRAM

Contributed Papers

Arranged by T. PAUL MASLIN
(Curator of Zoological Collections)
Univ. of Colorado Museum, Boulder, Colorado

****
MONDAY, DECEMBER 28 Conrad Hilton/Parlor 413
****

MORNING SESSION. Chairman: T. PAUL MASLIN

10:00 FOOD ECOLOGY OF A TROPICAL FROG, LEPTODACTYLUS FALLAX. Garnett R. Brooks (College of William and Mary)

10:20 SUMMER FOOD HABITS OF RANA SEPTENTRIONALIS AND SYMPATRIC RANA PIPIENS IN MINNESOTA. Stanley E. Hedeen (Xavier University)

10:40 THE DAILY ACTIVITY AND ECOLOGY OF CALLISAURUS AT THE NEVADA TEST SITE. Wilmer W. Tanner (Brigham Young University)

11:00 AMPHIBIANS, REPTILES AND FUNGUS OF THE GENUS BASIDIOBOLUS. Max A. Nickerson and James A. Hutchison (Arkansas State University)

11:15 PRECISION OF BEHAVIORAL THERMOREGULATION IN LIZARDS. Bayard H. Brattstrom (California State College, Fullerton)

11:35 COMPARATIVE TONGUE HISTOLOGY OF THE LIZARDS CNEMIDOPHORUS TIGRIS (TEIIDAE) AND SCELOPORUS JARROVI (IGUANIDAE). Stephen R. Goldberg (Whittier College)

11:55 COMPARATIVE HEMATOLOGY OF SOME NEOTROPICAL FROGS. Duvall A. Jones (Carnegie-Mellon University)

****

AFTERNOON SESSION. Chairman: HYMEN MARX (Field Museum of Natural History)

2:00 MORPHOLOGY AND PHYLOGENETIC RELATION OF THE VIPERID SNAKE, AZEMIOPS FEAE. Karel Liem, Hymen Marx and George Rabb (Field Museum of Natural History and Chicago Zoological Park)

2:20 MOVEMENTS OF THE BOX TURTLE, TERRAPENE CAROLINA. Robert Madden (Queens College)

AFTERNOON SESSION (CONTINUED).

2:40 THE PHYLOGENETIC IMPLICATIONS OF BODY MOVEMENTS IN DISPLAYING SCELOPERINE LIZARDS. James R. Purdue and Charles C. Carpenter (University of Oklahoma)

3:00 HOME RANGE OF SCELOPORUS UNDULATUS ERYTHROCHEILUS MASLIN. John W. Ferner (University of Colorado)

3:20 HEARTRATE AND AGGRESSION IN AMPHIBOLURUS BARBATUS. Jan F. Sassaman and Charles C. Carpenter (University of Oklahoma)

3:35 PREDATION RESPONSE OF THE PANCAKE TORTOISE MALACOCHERSUS TORNIERI. L. C. Ireland (State University of New York, Buffalo)

3:55 AGGRESSIVE DISPLAYS IN THE VARIABILIS GROUP OF SCELOPORUS (IGUANIDAE). Charles C. Carpenter (University of Oklahoma)

4:15 SEA SNAKE COLLECTION AND VENOMS. Anthony T. Tu (Colorado State University)

****
TUESDAY, DECEMBER 29 Conrad Hilton/Parlor 413
****

MORNING SESSION. Chairman: WILMER W. TANNER (Brigham Young University)

9:30 BODY SIZE AND DISTRIBUTION OF WHIPTAIL LIZARDS. Kenneth K. Asplund (Virginia Commonwealth University)

9:50 REPRODUCTION IN THE CANEBRAKE RATTLESNAKE, CROTALUS HORRIDUS. J. Whitfield Gibbons (Savannah River Ecology Laboratory)

10:10 MICROGEOGRAPHIC VARIATION IN DESMOGNATHUS FUSCUS. George W. Folkerts (Auburn University)

10:30 A POPULATION OF OZARK HELLBENDERS. Max A. Nickerson and Charles E. Mays (Arkansas State University)

10:50 A NEW LIMBLESS SKINK FROM THAILAND WITH COMMENTS ON THE GENERIC STATUS OF THE LIMBLESS SKINKS OF SOUTHEAST ASIA. W. Ronald Heyer (Pacific Lutheran University)

11:10 LIFE HISTORY AND POPULATION STRUCTURE OF DESMOGNATHUS OCHROPHAEUS INHABITING WET ROCK FACES. Stephen G. Tilley (Smith College)

11:30 BUSINESS MEETING Conr.Hilt./Parl.413
****

ABSTRACTS OF PAPERS

ASPLUND, KENNETH K. (Va. Comm. U.). Body size and distribution of whiptail lizards.

Among bisexual species of Cnemidophorus (Teiidae) in the arid southwest, the largest forms are generally restricted to the shadiest habitats. Small body size has apparently evolved in response to the development of desert scrub in the late Pleistocene. During above-ground activity periods, larger whiptails spend more time in shaded microhabitats and less time basking than do smaller whiptails. Both sizes have similar daily activity patterns. Eccritic body temperatures and thermal tolerance limits are similar in both size classes. The observed differences in behavior are presumably due to a relatively greater thermal lag and a more effective muscular thermogenesis in the larger lizards.

BRATTSTROM, BAYARD H. (Calif. State Coll.). Precision of behavioral thermoregulation in lizards.

Several recent experiments have indicated the importance of learned behavior in determining the precision with which such lizards as Sceloporus magister and Dipsosaurus dorsalis can behaviorally thermoregulate. In one hour (only) daily exposure to a photothermal gradient, the lizards become more effective in learning to use the thermal mosaic of the gradient. As a result the variation in body temperature is less on each subsequent day. In Sceloporus magister the preferred body temperature also drops on each subsequent day. The size, shape, and thermal parameters of thermal gradients will be discussed in light of these and other experiments.

BROOKS, GARNETT B. (Coll. William & Mary). Food ecology of a tropical frog, Leptodactylus fallax.

(abstract not received)

CARPENTER, CHARLES C. (U Oklahoma). Aggressive displays in the variabilis group of Sceloporus (Iguanidae).

(abstract not received)

FERNER, JOHN W. (U. Colo.). Home range of Sceloporus undulatus erythrocheiles Maslin.

This is a rock inhabiting lizard of the eastern Colorado foothills. An ecological study of one population of this lizard has continued in Boulder County, Colorado since 1969. Individuals were captured, marked, released and reobserved within the 3/4 acre study area. Ninety-seven lizards (53 males and 44 females) have been captured, 32 males and 19 females being observed at least three times in any one year. The home range size of these lizards was calculated with a polygon method and a minimum of ten observations was used to give a reliable calculation. On the basis of ten or more observations, resident adults (over 50 mm snout-vent length) had an average home range size of 0.08 acres for 10 males and 0.03 acres for 9 females. The large degree of male home range overlap suggests that home range is not equal to territory in these lizards. A promiscuous mating system is implied from the overlap of male and female home ranges and from behavioral notes.

FOLKERTS, GEORGE W. (Auburn U.). Microgeographic variation in Desmognathus fuscus.

An analysis of geographic variation in pattern characteristics of populations of the ravine ecotype of Desmognathus fuscus in the mid-South revealed the presence of microgeographic races which in some instances are remarkably distinct from one another. Other characters analyzed did not necessarily vary geographically in a pattern concordant with those demonstrated by pattern and pigmentation. The ranges of the microgeographic races partially coincide with the boundaries of physiographic or biotic regions. Similarities and dissimilarities among the populations can be correllated with conjectured past dispersal pathways. Some workers have looked at these populations from a purely phenetic viewpoint and considered them to be species or subspecies, an approach which creates additional obfuscation of relationships in a genus where confusion is already rampant.

GIBBONS, JAMES W. (Savannah River Ecol. Lab.). Reproduction in the canebrake rattlesnake, Crotalus horridus.

Mean litter size of the canebrake rattlesnake in South Carolina is 12.5 and does not increase as a function of female body size. Follicular atresia occurs and is possibly a mechanism whereby litter size is optimized in accord with environmental conditions. A biennial, or possibly triennial, reproductive cycle occurs in female canebrake rattlesnakes in this region. Size of the fat bodies seems related to reproductive state of the individual. Amount of fat increases during the first summer of yolking but is significantly reduced in females containing embryos the following spring. Immediately after parturition in late summer the fat stores are extremely diminished. Canebrakes are over 100 cm in snout-vent length and weigh over 700 g when mature. They presumably have their first litter in late summer four years after birth. Males are mature at 90-100 cm in length and are reproductively active in their fourth year. Size superiority in combat dances may be the positive factor that has favored selection for larger individuals of this sex.

GOLDBERG, STEPHEN R. (Whittier Coll.). Comparative tongue histology of the lizards Cnemidophorus tigris (Teiidae) and Sceloporus jarrovi (Iguanidae).

The distally forked tongue of Cnemidophorus tigris is abundantly supplied with nerves and sensory fibers. It contains papillae of the filiform variety which are covered by stratified squamous epithelium. Mucous cells are present in the crypts between the posterior papillae. Sceloporus jarrovi possesses an unforked tongue containing villus-like papillae. The heads of the papillae are capped by squamous cells; the shaft is covered by columnar epithelium. No sensory fibers were seen. Moderate quantities of mucous glands are found in the squamous epithelium which covers the posterior portions of the tongue. Differences were noted in taste corpuscle morphology. In C. tigris they are round, whereas those of S. jarrovi are flask shaped. Both contain sensory and supportive cells. Sensory cells of S. jarrovi end in peg-like processes. Those present in C. tigris lack these processes.

HEDEEN, STANLEY E. (Xavier U.). Summer food habits of Rana septentrionalis and sympatric Rana pipiens in Minnesota.

Stomach content analysis revealed animal material in all 74 R. septentrionalis examined. Plant material occurred in 67 stomachs. Diet differences among mink frog populations in Itasca State Park were due to differences in habitat and seasonal food availability. R. pipiens joined resident R. septentrionalis in aquatic habitats during August. In Bog D, mink frogs located within 10 feet of shore primarily ingested aquatic prey while sympatric leopard frogs primarily ingested terrestrial prey. In Lake Itasca, mink and leopard frogs located more than 10 feet from shore contained similar numbers of all major food items except Coleoptera larvae and Trichoptera adults. Higher incidence of these aquatic prey in R. septentrionalis may reflect interspecific differences in feeding behavior. The water surface foraging behavior of R. septentrionalis, a very aquatic species, is probably more efficient than that of R. pipiens, a semi-aquatic species with a wide habitat range.

HEYER, W. RONALD (Pacific Lutheran U.). A new limbless skink from Thailand with comments on the generic status of the limbless skinks of Southeast Asia.

Three limbless skinks have been known previously from Thailand. Discovery of a new species of limbless skink in Thailand initiated a review of the limbless skinks of the region. Based on characters of skeletal and external morphology, the conclusion is reached that each of the Thai limbless skinks represents an independent invasion of the fossorial habitat. Furthermore, the Thai forms represent distinct evolutionary lineages from the Australian limbless skinks which previous workers have placed in a common genus.

IRELAND, LEONARD C. (S.U.N.Y. at Buffalo). Predation response of the pancake tortoise Malacochersus tornieri.

Early field observers reported that the soft-shelled, East African tortoise Malacochersus tornieri wedged itself into narrow rock crevices, presumably to escape predators,

by inflating its body with air and using its legs as struts. In the present experiment 6 Malacochersus had their lungs catheterized to permit direct recording of intrapulmonary pressure and were equipped with chronic electrodes to permit the recording of heart rate and various muscular activities. These parameters were recorded while the animal was pulled from an artificial crevice. The subjects' behavior was simultaneously recorded on 16mm. film and video tape. While being pulled from the crevice all subjects were observed to dig the claws of their forelimbs into the ground and rotate their forelimbs outward, wedging the body into place. At such instances a decrease in pulmonary pressure was often noted, reflecting the extent to which the position of the pectoral girdles changed relative to the internal space of the shell. Never in over 100 trials was a significant and sustained increase in pulmonary pressure associated with the wedging action. These observations suggest a different interpretation of the significance of the soft-shell of Malacochersus.

****

JONES, DUVALL A. (Carnegie-Mellon U.). Comparative hematology of some Neotropical frogs.

Erythrocyte count and size, hematocrit, and hemoglobin concentrations are given for twenty-four species of Neotropical frogs in five families. Erythrocyte counts and hemoglobin concentrations for some of these tropical species exceed those reported for frogs of temperate North America. There does not appear to be a correlation between any of these measurements and the accumulation of biliverdin in the tissues.

****

LIEM, KAREL, HYMEN MARX and GEORGE B. RABB (Field Museum of Natural History and Chicago Zool. Park). Morphology and phylogenetic relations of the viperid snake, Azemiops feae.

Azemiops is a primitive viperid, as shown by the small proportion (18%) of 50 skeletal and integumental characters occurring in a derived state. In several features reputedly separating the crotalines and viperines, Azemiops shows intermediate conditions or shares a state with one group. Azemiops also exhibits four substantial characteristics unique among the Viperidae. Separate subfamily ranking best indicates our assessment of its phylogenetic relationships.

NICKERSON, MAX A. and JAMES A. HUTCHISON (Ark. St. U.). Amphibians, reptiles and fungus of the genus Basidiobolus.

More than 400 specimens of amphibians and reptiles, representing 53 taxa and a variety of ecological relationships, were surveyed for the fungus, Basidiobolus ranarum. B. ranarum was isolated from species occupying a broad range of ecological situations, varying from totally aquatic to semi-arboreal and subterranean forms. B. ranarum has been described as an etiological agent in salamanders but appears a common saprobe in many amphibians and reptiles.

NICKERSON, MAX A. (Ark. St. U.) and CHARLES E. MAYS (DePauw U.). A population of Ozark hellbenders.

During the summers of 1969 and 1970 a population of the Ozark hellbender was studied using scuba gear and tag recapture methods. Data presented include estimates of their numbers, biomass, density, and various aspects of natural history.

****

PURDUE, JAMES R. and CHARLES C. CARPENTER (U. Okla.). The phylogenetic implications of body movements in displaying Sceloperine lizards.

Body motion of displaying males was quantified by calculating two ratios representing shoulder and hip movement for each push-up. Within the Uta/Urosaurus complex two distinct groups were revealed. Species of Urosaurus formed one group by displaying with considerable hip motion; species of Uta (sensu Mittleman) formed the second group by displaying with little hip motion. Collectively these two genera greatly exceeded the range of comparable values for more than 20 species of Sceloporus. These data supported the division of Uta and Urosaurus. Present data further indicated much similarity in the display between the merriami and maculosus groups of Sceloporus and Urosaurus, supporting the view that Urosaurus stemmed from this branch of Sceloporus. A similar situation was noted between the Sceloporus variabilis group and Uta. The form mearnsi had much display motion similarity with species of Uta.

TILLEY, STEPHEN G. (Smith Coll.). Life history and population structure of Desmognathus ochrophaeus inhabiting wet rock faces.

Populations of the salamander Desmognathus ochrophaeus inhabiting wet, vertical rock faces in the vicinity of Mt. Mitchell, North Carolina were sampled and information on size and age at maturity was compiled. Size at maturity was found to increase with increasing elevation and at a given elevation individuals were found to mature at smaller body sizes than they do in nearby woodland populations. Two populations inhabiting rock faces at 5025 and 3500 feet above sea level yielded sample sizes sufficient to permit determination of age at maturity and juvenile growth rates from juvenile size-frequency distributions. In the higher elevation population sexual maturity is attained at larger body sizes, which in turn are attained by delaying sexual maturity about one year relative to its occurrence in the lower population. The juvenile growth rates of the two populations are similar to one another and to those estimated for nearby woodland populations.

TU, ANTHONY T. (Colo. St. U.). Sea snake (Hydrophiidae) collection and venoms.

In total, 2,600 and 6,000 sea snakes were collected in 1967 and 1969 respectively, in the different parts of Southeast Asia. In 1969, we collected 4,305 Lapemis hardwickii among the 5,306 sea snakes captured in the Gulf of Thailand. The predominant sea snake inside the caves of Gato Island was Laticauda semifasciata with a smaller number of Laticauda colubrina. The majority of sea snakes collected in Amami Island were Laticauda semifasciata, but were much smaller in size and length from those of Gato Island. Pelamis platurus is quite common along the Northern Formosan coast while Hydrophis cyanocinctus is quite common along the south-western Formosan Coast. Most of the sea snakes in Hong Kong waters are of the genus Hydrophis. The toxic components of venoms were isolated from E. schistosa, L. hardwickii, and L. semifasciata. They have a molecular weight of about 7,000 with 61 or 62 amino acid residues, and an isoelectric point of 9.2 to 9.9. The fact that the purified toxins are devoid of enzymatic activity suggests that toxins are non-enzymatic in nature. The tryptophan residue is necessary for the toxic action of sea snake venom as the chemical modification of tryptophan residue of purified toxin completely destroyed toxic action.

ANNOUNCEMENT

The Society for the Study of Amphibians and Reptiles is pleased to announce the new Editorial Committee for its Miscellaneous Publications series (which includes the Facsimile Reprints in Herpetology program). The committee will serve for one year beginning January 1, 1971.

Miscellaneous Publications:
Facsimile Reprints in Herpetology

KRAIG ADLER, Editor
Department of Biology
University of Notre Dame
Notre Dame, Indiana 46556

Editorial Committee
ROBERT MERTENS
Forschungsinstitut Senckenberg (Germany)
P. E. VANZOLINI
Universidade de Sao Paulo (Brazil)
RICHARD D. WORTHINGTON
University of Texas at El Paso

The Society wishes also to publicly record its gratitude to Carl Gans and I. S. Darevsky for their service on this committee during 1969 and 1970.

MEMBERS DESIDERATA

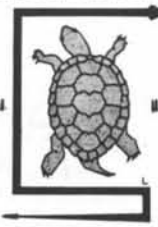
D. BRUCE MEANS (Tall Timbers Research Station, Route 1, Box 160, Tallahassee, Fla. 32301) would like to obtain data from independent collectors on reptiles and amphibians from western Florida, southern Alabama and southern Georgia. These data are needed in the compilation of distribution maps for herps from this area. A study will be terminated with the publication of an annotated checklist of the reptiles and amphibians of the Tall Timbers region.

LOST MEMBERS

Mail addressed to the following members or "Catalogue" subscribers has been returned, marked "Address Unknown." Information on current addresses should be forwarded to the Editor.

VICTOR L. CAMP, 207 West Cherry Street, Carbondale, Ill. 62901.

DOUGLAS M. LAY, 1369 E. Hyde Park, Apt. 908, Chicago, Ill. 60615.



M. B. MITTLEMAN, 3730 Lake Shore Drive, Chicago, Ill. 60613.

FIELD GUIDE NEARING COMPLETION

Work on the final phases of the second and completely revised edition of the Conant Field Guide (Houghton Mifflin) is now well advanced. The new book, which will bear the title of A Field Guide to the Reptiles and Amphibians of Eastern and Central North America, will include all the species and subspecies occurring in western Texas and northward that currently are not covered in either the Stebbins or the Conant Guides.

Roger Conant expects to spend a large part of 1971 preparing distribution maps, and he requests that information about range extensions or pending taxonomic changes be sent to him as soon as possible. Publication of his Field Guide is expected in late 1972 or early in 1973, but the manuscript, maps, and art work must all be submitted to the publisher a full year in advance. Address him as follows:

ROGER CONANT
Hyla Holler, Taunton Lakes
Marlton, New Jersey 08053

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The CATALOGUE has published its 100th account -- along with a Table of Contents and a new title page. The last issue consists of:

91. ***Plethodon vandykei***, by Edmund D. Brodie, Jr. and Robert M. Storm.
92. ***Hyla septentrionalis***, by William E. Duellman and Ronald I. Crombie.
93. ***Bufo alvarius***, by M. J. Fouquette, Jr.
94. ***Bufo valliceps***, by Kenneth R. Porter.
95. ***Coleonyx***, by James R. Dixon.
96. ***Coleonyx variegatus***, by James R. Dixon.
97. ***Gerrhonotus kingii***, by Robert G. Webb.
98. ***Thamnophis proximus***, by Douglas A. Rossman.
99. ***Thamnophis sauritus***, by Douglas A. Rossman.
100. ***Clemmys marmorata***, by R. Bruce Bury.

The first issue for 1971 will include Cryptobranchus, two Plethodon accounts, two frog accounts, two turtle accounts, and Anolis distichus.

CURRENT HERPETOLOGICAL TITLES, XII: 1969 - 1970

Herpetological Information Search Systems
American Museum of Natural History
New York, N. Y. 10024

In the last twelve issues we brought to your attention some 11,500 current titles in the pages of this journal. This list brings the titles of papers published in 1969 to a new high for one year, 3,950 and still more to go.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts-Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses especially.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any current paper (e.g., 1969-1970) that is concerned with a member of a Recent order of amphibians or reptiles.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This twelfth list contains titles of books and articles that have come to our attention during the period 21 July 1970 through 7 October 1970. The list is divided into two separate, alphabetically arranged sections: one for titles published in 1969, and one for titles published in 1970.

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and T. Shaman. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. Dr. Robert W. Winter provided us with translations of titles, abstracts and papers from Slavic languages. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

Members of the Herpetology Department and the Library staff of the Museum have continued to aid our efforts. No commercial computer service yet offers all of the facilities that we need, however, and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 26 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

IF YOUR MAILING ADDRESS
HAS BEEN CHANGED.....

...It may be because HISS is handling the SSAR mailing list now. As a part of our continuing effort to gather information needed by people who are interested in amphibians and reptiles, HISS has begun preparation of a comprehensive world list of herpetologists.

As an initial step, we have consolidated the mailing lists of the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES and the CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES. Other names are being added as time permits.

JOURNALS INCLUDED

Listed below are the 239 issues of 161 different journals in which articles relating to amphibians and reptiles were found during this quarter. This list is intended, not only as an indicator of the highly scattered nature of articles pertaining to these animals, but as a warning. It is unlikely that any one library will have all these journals. None of the large medical, biological or biochemical abstracting services cover all of these journals nor does Zoological Record. How can one find them? Can we ignore them? If someone thinks that some at least can be ignored, which ones? If you have any ideas let us know.

LIST OF GAZETTEERS

The Department of the Interior, as one of its major responsibilities for standardization of Federal usage of both domestic and foreign geographic names, established the United States Board on Geographic Names. This board published the following gazetteers which we found very useful in tracing localities in foreign countries. Most of them are available free from U.S. Army Topographic Command, 6500 Brooks Lane, Washington, D.C. 20315. Some of them are available for a nominal charge from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Each gazetteer contains thousands of entries for places and features. Entries include standard names approved by the above board and unapproved variant names, the latter cross-referenced to standard names. Reference to the maps used for the basic names covered is given in each gazetteer. Since practically all geographic terms have varied meanings, the senses in which the designated terms are used and the range of features to which they are applied in each gazetteer are stated to reduce ambiguity. The distinctions that can be made in a given gazetteer will vary with the quality of the maps of the area and with the nature of the entities that are named.

THE "QUADRIFURCATE" HEMIPENIS OF TROPIDOPHIS

Frances W. Gibson

A "quadrifurcate" hemipenis (i.e., a bilobed hemipenis in which the lobes are again divided to form two pairs of secondary lobes) was described in certain species of the boid genus Tropidophis by Stull (1928). She described in detail the hemipenis of all the species recognized in this genus at that time, except the mainland species T. pauciscuamous and T. taczanowski. She illustrated the organ in nine forms, showing it in the in situ inverted position, split for examination.

She used hemipenial form in her separation of Tropidophis into the "Maculatus Group," defined as having bifurcate, longitudinally laminate hemipenes and smooth scales (maculatus and, tentatively, pauciscuamous), and the "Pardalis Group," with quadrifurcate, flounced hemipenes and keeled scales (pardalis, melanurus, wrighti, semicinctus, and, tentatively, taczanowski).

Bailey (1937) accepted Stull's hemipenial descriptions and subgeneric groups. Schwartz and Marsh (1960), however, disagreed both with her groupings and her descriptions of the hemipenes. After stating that keeled and smooth scales were intraspecifically variable, they commented about her observations of the hemipenis (1960: 53-54):

> Stull's second character, that of the forking of the hemipenis, is apparently equally untenable. We have examined by dissection the hemipenes of all forms pertinent to the study. In addition, a few recently preserved specimens have the hemipenes extruded. In no cases have we seen quadrifurcate hemipenes. The appearance of double bifurcation is at times given by the bands of retractor muscle fibers, but in every case where this superficial resemblance to a quadrifurcate hemipenis was seen upon dissection, careful observation revealed that the hemipenis was in actuality bifurcate. Extruded hemipenes (*nigriventris, barbouri, jamaicensis, pardalis*) likewise are uniformly bifurcate and show no evidence of the quadrifurcate condition. It is pertinent to point out here that Stull (*op. cit.*:11) cited only a single male (MCZ 12445) of *maculatus* examined; we have studied this snake. It lacks spurs, and the tail has been dissected; what were apparently considered as being hemipenes are in reality the paired scent glands, filled at present with much fragmented and solidified musk. The snake is obviously a female; however, dissection of available *maculatus* males reveals that they do indeed have a bifurcate hemipenis, as do all other known members of the complex.

This would appear to settle the matter, and indeed no further investigations of the hemipenis of Tropidophis have been reported.

While preparing hemipenes for the Genera of Reptiles Project, I everted completely the hemipenis of Tropidophis melanurus (Fig. 1). Though the hemipenis is small, thin and delicate, there is no question of the presence of secondary division of the primary lobes, giving the "quadrifurcate" condition described by Stull (1928). This discovery raised the question of the validity of Stull's other observations.

PROCEDURE AND DESCRIPTIONS

The only pertinent specimens readily available had been preserved with the hemipenes in the inverted state. However, by soaking them in glycerine, and then in a solution of trisodium phosphate and "Calgonite," (Gibson, 1970: MS) it was possible to soften the tissues sufficiently for eversion. Everting the hemipenis is a laborious process in such snakes as these in which the organ is small and delicate. However, it is well worth-while, because it resolves such questions as to the organ involved (muscle fibres do not evert; scent glands have no characteristic ornamentation), and its shape and structure. Four specimens of three species were everted by this method. Their descriptions, and some discussion of a fifth individual follow.

Tropidophis melanurus (AMNH 82881, 82882).

-- The everted hemipenis is eight subcaudals long (about 13 mm). The primary division into two lobes is at about the mid-length of the organ. Distally the primary lobes redivide, forming two pairs of secondary lobes that occupy about the apical one-eighth of the organ. The sulcus forks at the level of the bilobation. Its branches extend up the medial surface of the

FIGURE 1. Everted left hemipenis of Tropidophis melanurus (AMNH 82882). Note the presence of secondary lobes.

primary lobes (centripetal). The lips of the sulcus become small and indistinct on the secondary lobes. The sulcus appears to subdivide on the right primary lobe of the hemipenis of AMNH 82881, but this cannot be seen on the left lobe, or on either lobe of the hemipenis of AMNH 82882. /Stull (1928: 40) reported that the sulcus did not divide in this species./

The hemipenis is ornamented with flounces and papillae. Scattered large papillae are found proximally. Distally these join to form pronounced transverse flounces. The flounces are reduced in size and extend longitudinally on the distal parts of the primary lobes and on the secondary lobes. Several large papillae are near the distal end of the basal region on the sulcate side of the organ; a single large papilla is on the asulcate side.

Apparently Stull cut off part of the base of the organ, thus altering her proportional

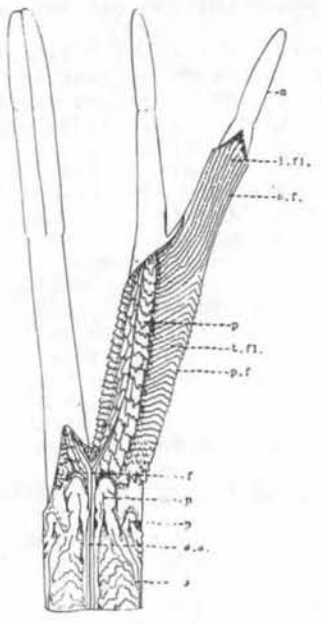

FIGURE 2. Hemipenis of Tropidophis maculatus from Stull (1928: Fig. 9).

descriptions (e.g., the point of forking of the sulcus becomes about one-half the length, instead of one-third). Apparently, also, the four large papillae on the base which she mentions and figures (1928: Fig. 9) become bulges when the organ is inflated. Otherwise, however, the organ agrees with her description and figure in all important respects (Fig. 2).

Tropidophis pardalis (AMNH 78605).

-- The everted hemipenis is eight subcaudals in length (approximately 16 mm). In form it corresponds very closely to Figure 2 in Stull (1928), and to my figure of I. melanurus (Fig. 1). Again, the overall proportions are changed through the loss of the base of the organ. The secondary lobes (giving a "quadrifurcate" organ) are clear. The lips of the sulcus appear to divide distally, with one lip extending up each of the secondary lobes.

Tropidophis canus curtus (AMNH 93001).

-- The everted hemipenis is six subcaudals long (approximately 11 mm). The form corresponds closely to that of I. melanurus and I. pardalis. /In fact, this form was considered a subspecies of I. pardalis by Stull (1928: Fig. 4). See Stimson (1969: 32-38) for a recent arrangement./ The longitudinal flounces occupy about half the length of the primary lobes, rather than beginning near the distal ends as in I. melanurus. As in I. pardalis, the lips of the sulcus separate at the point of subdivision of the primary lobes, one lip extending onto each of the secondary lobes.

Tropidophis maculatus (MCZ 12445).

-- I agree with Schwartz and Marsh (1960), as quoted above, that this specimen is a female. Whether there was a mixup of specimens or numbers cannot be determined at this late date. However, I do not believe that Stull (1928) could have drawn her Figure 1 from the scent glands of a specimen which were still "filled with...musk" when it was examined by Schwartz and Marsh.

SUMMARY AND CONCLUSIONS

The hemipenes of four specimens of Tropidophis were everted to determine the validity of Stull's (1928) descriptions of "quadrifurcate" hemipenes in this genus of snakes -- a hemipenial form otherwise unknown among snakes. In contrast to the statements of Schwartz and Marsh (1960), the hemipenes were found to be "quadrifurcate" (probably better called quadrilobate) in I. melanurus, I. pardalis, and I. canus, as described by her.

Stull (1928: 10) described the hemipenis of I. maculatus as bilobed; this was, in effect, "confirmed" by Schwartz and Marsh (1960: 54). However, in view of the apparent mixup of Stull's specimens and the unreliability of hemipenial descriptions in the literature, fresh material is badly needed for proper examination and description.

It seems only just to point out that the specimen used for illustration (Fig. 1) was from a snake collected and preserved (with the hemipenes partly everted) by Albert Schwartz. It is unfortunate that Miss Stull did not live to see her observations corroborated.

ACKNOWLEDGEMENTS

I thank Ernest E. Williams, Museum of Comparative Zoology at Harvard University (MCZ), and Richard G. Zweifel, of this Museum (AMNH), for their permission to utilize specimens from collections under their supervision. I also thank H. G. Dowling, I. Gilboa, and Dr. Zweifel for their comments on the manuscript.

INDIVIDUALS

AND

INSTITUTIONS

****

The ORGANIZATION FOR TROPICAL STUDIES, a consortium of 27 Latin American and U.S. universities, will offer its ninth year of graduate courses in tropical science in Central America. Among the course offerings are Terrestrial Biology and Ecology. Catalogue and applications may be obtained from: OTS North American Office, 5900 S.W. 73rd St., South Miami, Fla. 33143.

NATHAN W. COHEN (Extension, U Cal, Berkeley) exhibited 94 of his outstanding color photographs of amphibians and reptiles at the U.S. National Museum (Washington) in July and August, and at the American Museum of Natural History (New York) in October and November.

THOMAS C. CHENG has been named director of the new INSTITUTE FOR PATHOBIOLOGY at Lehigh University, Bethlehem, Pa. Among other projects, the Institute will investigate rejection mechanisms in cold-blooded vertebrates and tumors and cancers in "lower forms" of animals.

ROBERT E. GORDON (Notre Dame U) has been made a member of the U.S. National Committee of the International Union of Biological Sciences.

E. PETER VOLPE (Newcomb Col, Tulane U) was reappointed to represent the AIBS on the U.S. National Commission for UNESCO.

STEPHEN G. TILLEY (Ph D, U Mich, 1970) was appointed assistant professor, Dept. Biological Sciences, SMITH COLLEGE. His dissertation was, "Aspects of the reproductive and population ecology of Desmognathus ochrophaeus in the southern Appalachian Mountains." He continues to work on the population ecology and demography of D. ochrophaeus populations on wet rock faces in the southern Appalachians.

SOPHIE JAKOWSKA (27 W 96th St, NYC 10025) has suggested the establishment of a "BUFO MARINUS INFORMATION EXCHANGE" to aid in evaluating the research value and potential of this widespread species.

JAMES BERRY and CULVER GIDDEN (Fla. State U) are investigating a population of Clemmys guttata from near St. Marks, Fla. and Jim is contemplating study of Pleistocene turtles from the Aucilla River.

BRUCE MEANS (Fla. State U) is about halfway finished with an annotated checklist of the reptiles and amphibians of the Tall Timbers region. Work on that manuscript is presently halted until January while he finishes his Master's thesis on the genus Desmognathus in Florida.

CLIVE LONGDEN (Fla. State U) is studying the ecology and morphological variation of Hyla andersoni in Florida.

ANGUS d'A. BELLAIRS has been appointed the first Professor of Vertebrate Morphology at the University of London.

PAUL F.A. MADERSON and STANLEY N. SALTHE have been raised to Associate Professor rank, and thus made members of the tenured faculty of Brooklyn College.

WALTER AUFFENBERG (Fla. State Mus., Gainesville) recently returned from 11 months on Komodo Island with much information on ecology and life history of the giant monitor. He hopes to return to the region in 1971.

WILLY BECAK (Inst. Butantan, Sao Paulo) attended the AIBS and SSAR meetings, and visited a number of institutions before returning to Brazil.

EAST AFRICAN STUDY TOUR

The Faculty of Zoology and the Office of International Programs of THE OHIO STATE UNIVERSITY (Columbus, Ohio 43210) announce plans for a study tour to Kenya and Tanzania, Spring Quarter, 1971. The tour is entitled "Ecological and Biogeographic Problems in East Africa", and is open to selected advanced undergraduate and graduate students throughout North America. Up to 15 quarter hours credit can be earned. Participants will have to register at OSU, spend 5 weeks in preliminary course work on campus, then 7 weeks in Africa, the last 10 days of which are free time. The charter plane (Pan Am Boeing 707) leaves Columbus May 5 and returns on June 23. Present estimates for cost of round trip to Nairobi and expenses in Africa are about $1,200 - 1,300 per student, plus expenses on campus; or, a total estimate of $2,000 for the entire quarter.

Faculty personnel are Dr. BARRY D. VALENTINE, past chairman of section A, (Systematics, Morphology, and Evolution) of the Entomological Society of America, life member of the American Society of Ichthyologists and Herpetologists, fellow of the Herpetologists League, etc., principal interests in systematics and biogeography; and Dr. ABBOT S. GAUNT, member American Society of Zoologists, Society for the Study of Evolution, Society for Systematic Zoology, American Ornithologists Union, Cooper Ornithological Society, Wilson Ornithological Society, New York State Postdoctoral Fellow, Faculty Research Awards for studies in avian anatomy, principal interests in functional morphology, ecology, and systematics.

DEADLINE for applications is 1 February 1971.

MALAYSIANS WITNESS FROGS' WAR TO DEATH

KUALA LUMPUR, Malaysia (AP) — More than 3,000 frogs of four different varieties fought a furious battle lasting more than six hours, local newsmen reported Sunday. They said the frog war took place in a swampy valley beside a Hindu temple at a rubber estate near Sungai Siput, 100 miles north of Kuala Lumpur.

At first, only about 50 frogs were involved but soon the numbers swelled, the newsmen reported, adding that about 1,000 people assembled to watch the frogs bite and tear at each other. Many were dead at the end of the battle.

Maria Soosay, 30, who has lived for years near the area, said the war is almost an annual event.

"But they have been small fights. This is the biggest so far," he said.

Local superstition has it that frog wars come just before big national disasters. Just 12 days before the Malay-Chinese race riots May 13 last year a small frog war was reported to have taken place at Butterworth, 200 miles northwest of here.

Other frog wars have been reported at various times in different parts of west Malaysia. No one has so far come forward with any theory why such battles take place.

A Jump Ahead of Toads

NEW YORK POST, WEDNESDAY, SEPTEMBER 23, 1970 14

PLEASANTVILLE, N. J. (AP)—"The Invasion of the Toads" sounds like something you'd see on a late night TV horror show, and a horror it is for Mr. and Mrs. Fred Miller of this small Jersey town.

The toads have invaded, and they are atop the TV, in front of it, in the bathroom and all over the house.

For the past three summers the Millers' ranch-style home has been visited by toads, but only one or two at a time. This summer came the invasion.

Seventy-three were caught in the Miller home in one night. During a recent visit there were about 35 toads in the living room, 10 in the kitchen, 20 in the den and between five and seven in the bathrooms and bedrooms.

Miller said he has consulted with exterminators and agricultural officials. No one can explain how the toads get in the house or where they come from.

None of the houses in the neighborhood has the problem, and there are no swamps or marshes nearby.

TALL TIMBERS RESEARCH STATION

A research collection of reptiles and amphibians from western Florida, southern Alabama, and southern Georgia was built this past summer and is presently housed in the Museum of Tall Timbers Research Station, Route 1, Box 160, Tallahassee, Florida. The collection totaled about 5000 specimens on September 15th. Among the significant additions to the knowledge of the herpetology of Florida was the discovery of Desmognathus monticola from Escambia Co. (Means and Longden, HERPETOLOGICA, in press) and Hyla andersoni from Okaloosa Co. (Christman, QUART J FLA ACAD SCI, in press).

RESEARCH GRANTS

The AMERICAN MUSEUM OF NATURAL HISTORY invites applications for grants from the THEODORE ROOSEVELT MEMORIAL FUND, established to provide financial assistance to persons, especially younger scientists, conducting research on wildlife conservation or natural history (with zoological rather than botanical emphasis) in North America north of Mexico.

Grants are normally in small sums of not more than several hundred dollars, and are not usually made for salaries or the purchase of non-expendable equipment. The deadline for applications is 1 March, with awards announced in April. For application forms and additional information, write to:

Theodore Roosevelt Memorial Fund

BOOK REVIEW

****

A TAXONOMIC SURVEY OF COLOMBIAN ANURANS

Colombia is a land of complex physiography and diverse environments; these attributes, in combination with the important biogeographic situation, result in a fantastically diverse biota that has attracted the attention of biologists for many decades. Despite the potential for herpetological research in Colombia, relatively few herpetologists have made substantial contributions to our knowledge of the rich herpetofauna. Hno. Niceforo Maria has published numerous papers on the herpetofauna and has cooperated with various North American herpetologists, especially Emmett R. Dunn, who spent a year in Colombia in 1943 and 1944 and published many papers on the herpetofauna, principally in the journal Caldasia. Federico Medem continues to work on the turtles and crocodilians of Colombia.

The only faunistic study of amphibians and reptiles made in Colombia is that on the Sierra Santa Marta by Ruthven (1922, Misc. Publ. Mus. Zool. Univ. Michigan, no. 8, 69 pp.). Beginning in the mid-1950's, the late Doris M. Cochran began studying preserved frogs from Colombia. Subsequently, she was joined in her endeavors by Coleman J. Goin; together they attempted to survey the frogs of Colombia. Although the manuscript was essentially completed more than four years ago, the death of Dr. Cochran and various problems delayed the publication of the Frogs of Colombia until July, 1970.

The Frogs of Colombia is Bulletin 288 of the United States National Museum and consists of xii + 655 pages; the publication is available from the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402, for $4.

Following a brief introduction and dedication of the work to Hno. Niceforo Maria there are systematic accounts of 212 species and subspecies (28 taxa named as new), a gazetteer of Colombian collecting localities, and 68 plates. Interspersed in the text are 54 line drawings of frogs and one map. Accounts of the species of Hylidae, Centrolenidae, and Microhylidae were prepared by Goin; the other accounts were prepared by Cochran.

A comprehensive survey of a fauna should provide a summary of known information on the component species, accounts of the distribution of each taxon, discussions of the variation within and between populations, and most importantly keys, diagnoses, and illustrations that will permit the ready identification of specimens.

Cochran and Goin have been only partially successful in meeting these criteria. Although a list of locality records and specimens examined is appended to each species account, no statements of geographical distribution are given. Thus, the reader is compelled to plot the locality records and draw his own distribution map before arriving at an idea of the distribution of a given species. The authors had very limited field experience with Colombian frogs; this deficit is extremely apparent in their lack of knowledge of the animals in life and the nearly complete absence of statements on the ecology and life histories of the species.

The individual species accounts are variable in their usefulness; most are based on the detailed description of a single preserved specimen, in many cases the holotype, even though it may be in poor condition and even though fresh material was available. The practice of utilizing one specimen for a description is still widespread amongst older taxonomists despite George Myers' (Copeia 1950(3): 206) fiery critique:

> "It seems to have been the late Dr. Stejneger who initiated the present widespread American herpetological custom of composing a formal specific description from the detailed description of an individual specimen accompanied by notes on the variation of the other examples at hand. When used in the description of a type specimen, this method has the advantage of making clear the exact taxonomic characters of a specimen to which a name is tied, and avoids the possible danger that two different forms may be confused in the type description. But beyond this purely nomenclatural utility, the method has little conceivable value except to enable a hurried systematist to deliver an imposing description without taking time to examine in detail more than a single specimen. To use this method in a general systematic treatise, except as an adjunct, where the identity of types or aberrant individuals is in question, is little less than a fraud upon the scientific public, chiefly because the authors so using it are usually purely perfunctory or woefully remiss in giving the full details of variation seen in the bulk of their material. In a treatment of natural populations, what we are interested in is the nature of the population in hand, not of any individual, unless that individual happens to be intrinsically of special importance."

In most cases the species accounts are less than adequate for proper identification of specimens. This is due primarily to the authors' use of a single specimen for the description and entirely inadequate diagnoses (no diagnoses in accounts prepared by Cochran). Cochran's usage of Ridgeway's (1886, A nomenclature of colors for naturalists...) terminology for colors of preserved specimens is probably more detrimental than useful, because a worker having before him a living or recently preserved specimen can be led astray by colors based on old preserved specimens.

The keys to most of the large genera are not especially useful. Repeated attempts to key out known specimens of Atelopus and Eleutherodactylus have failed. The genus Hyla is divided into 22 groups, and keys are presented to the members of each of the 12 groups containing two or more species, but there is no key to the groups!

The taxonomy of some of the groups is erroneous. This is due to two factors. Firstly, the literature of the past five years has not been incorporated into the text; only one reference more recent than 1965 is listed in the Literature Cited. Secondly, the authors neglected several named taxa from adjacent geographical regions, especially Ecuador and Panama. The result is that names used by Cochran and Goin in some cases have been synonymized, or species named as new by them actually have older names based on specimens from other geographic regions.

The illustrations in the text vary from fair to poor; most of them lack depth and sufficient detail to be useful. The plates are categorically poor. This is not due to bad photography, but rather the subject. Black and white photographs of old, wrinkled, dried, and faded types show nothing more than the miserable state of the specimen.

The gazetteer and extensive literature cited are welcomed by the student of Colombian frogs; these will be very useful.

The Frogs of Colombia is a beginning at a synthesis of the large and diverse anuran fauna of northwestern South America. This reviewer cautions the users of the book to check carefully the identifications resulting from the use of the keys and to take into consideration that the authors have presented little data on intraspecific variation and have misapplied some specific names (these will be discussed in detail in a paper now in preparation). It is hoped that the present publication will provide the incentive for modern approaches to the study of Colombian anurans including the utilization of data on life histories, ecology, and mating calls.

Lest I be judged as an over-critical reviewer, I should like to point out that I am well aware of the tremendous amount of work that has gone into the Frogs of Colombia. Much of this kind of work is a thankless task that does not reap praise from modern biologists, but nevertheless is essential to the various disciplinary approaches now practiced by competent biologists who are neither able nor willing to undertake such a mundane chore. Thus, we should thank the late Doris M. Cochran and Coleman J. Goin for their efforts in making future work in Colombia a little bit easier for the rest of us.

BOOK REVIEW

****

A LABORATORY PERSPECTUS OF SNAKE ANATOMY. By Jonathan C. Oldham, Hobart M. Smith, and Sue Ann Miller. 1970. Stipes Publishing Company (10 Chester Street, Champaign, Illinois). v + 98 p. $4.75.

In spite of the considerable interest in snake anatomy and the rather large number of technical papers on some small aspect of snake anatomy, very few general accounts of the total gross anatomy of any one species of snake exist. The present account, based principally on Natrix rhombifera, is therefore welcome. I hope it will be successful -- so successful, in point of fact, that a revised edition is issued. A considerable number of revisions are in order.

Any inductive science demands two kinds of work, which may be called the journalistic and the philosophical. The journalistic aspect of science is the accurate reporting of the phenomena of the universe, and the philosophical aspect is the framing of explanations of these phenomena along certain rules of scientific explanation, such as minimum number and maximum generality of factors, etc. Human nature being what it is, anyone involved in the philosophical aspect is under temptation to dabble illicitly in the journalistic and make data fit an interesting explanation; and anyone involved in the journalistic aspect is always tempted (by shortness of attention span, if nothing else) to drop the often dull task of recording nature and relax in explaining nature. A perspectus of snake anatomy is a task in the journalistic aspect of science, and where the authors of the work under review have confined themselves to journalistic reporting they have performed a useful service.

Unfortunately, in sallying forth into philosophical aspects, they have wasted some opportunities for being useful and perform only a service that most herpetologists and many bright students could do for themselves, and do better. Thus a classification and phylogeny of snakes is presented without diagnoses or other justifying arguments, but as a list of names (including some invented "vernacular" names, such as "Dawn blindsnakes" for Anomalepididae, "Big jawed blindsnakes" for Leptotyphlopidae, and "Coralline snakes" for terrestrial proteroglyphs other than mambas). Although this classification is said to be "A commonly accepted arrangement," some features seem to be decidedly novel, such as division of the Crotalidae into "Subfamily Lachesinae (Bushmasters)" and "Subfamily Crotalinae (Viviparous pitvipers)." Without more explanation it is difficult to guess where oviparous Asiatic pit vipers without a rattle would be placed, since those who have

recognized Lachesinae and Crotalinae (e.g. Cope) have done so on the basis of absence or presence (respectively) of a rattle. Unexplained phylogenies and classifications are frequent appendices to popular natural histories that are concerned with interesting behaviour, folk-lore, etc. Such an appendix to a textbook on snake anatomy seems inexplicable unless the authors believe it unlikely that anyone has learned much from the preceding pages.

Although it might seem a good idea to include anatomical information on a variety of snakes, rather than on a single species, the results are unfortunate. The skull of Elaphe combined with the head muscles of Natrix is just the sort of imperfect information herpetologists have available in the literature, permitting no precise concept of muscle insertion and its effects on skull structure. (Incidently, the drawing of the head muscles of Natrix rhombifera does not closely resemble any of the nine specimens of this species I have dissected for head muscle study, and the drawings of the "skull of colubrine snakes, composite, largely of Pilot blacksnake, Elaphe obsoleta" show a number of oddities, such as an interdigitate and presumably rigid suture between the postorbital and parietal and a splenial bone extending into the lateral wall of the Meckelian canal.) This mixing of subjects results in a knowledge of snake anatomy similar to the concept of human anatomy in early Renaissance time, when pig-and-monkey-anatomy were confused with observations on human cadavers. A precise knowledge of man's place in the phylogeny of mammals would not have been possible without the careful culling out of non-human from human anatomy, and a full appreciation of the phylogeny of snakes is not made any easier by jumbling together the structures and adaptations of forms leading quite different lives and defending quite different ecologic niches.

The presence of a spinal accessory nerve in a snake was surprising to me, and I would have liked some documentation. Surprising also is the simple hypoglossal nerve issuing from a single foramen. (In the Natrix rhombifera I have dissected, two small rami of the hypoglossal issue from small foramina buried deeply in a common pit with the vagus foramen, while a larger branch issues from a foramen behind the compound vagus-hypoglossal passageway; another small foramen, dorsal to the hypoglossal foramen, is generally counted as one of the hypoglossal foramina, although the nerve issuing from it innervates epaxial muscles, principally the obliquus capitis; indeed, the last-mentioned nerve and large "main" hypoglossal remus seem to correspond to the first spinal nerve of lizards, incorporated into the cranial complex by backward extension of the skull, and the true hypoglossal is represented by the small branches associated with the vagus and unmentioned in the work under review.) The use of the term "otic nerve" for the auditory nerve of snakes is unfortunate, since "otic nerve" has a quite different meaning in fish anatomy: as the branch of the lateralis system associated with the facial nerve and innervating the neuromasts of the supratemporal canal. Identification of the lateral wing of the sphenoid with the pleurosphenoid seems equally erroneous and is certainly not supported by any developmental evidence; probably the best explanation of the lateral wing of the sphenoid of most snakes (it is absent in scolecophidian snakes) is Brock's, that it represents the basipterygoid process of lizards.

Questionable, but conventional and with some "outside authority," is the identification of small lymphoid bodies near the head as ultimobranchial bodies (they have the positional relationships of the anterior thymus bodies of lizards, and "ultimobranchial bodies" anterior to the thymus and thyroid seems contradictory in terms). The elongated dermal bone suspending the quadrate is called the supratemporal in the text and figures, in spite of Broom's demonstration that this bone in Squamata receives the insertion of axial muscles of the neck and is much more likely the tabular. (The bone of lizards usually called squamosal does fit the positional requirements of a supratemporal; probably no living squamatan has a squamosal bone, although the lower Triassic Prolacerta has an element in the expected position of a squamosal, on the lateral surface of the quadrate and well elevated above the jaw articulation, identified, I believe wrongly, as a quadratojugal.) On the other hand, Broom's identification of the reptilian vomer as a "pre-vomer" is accepted, even though the fossil record of the mammal-like reptiles is now so complete as to furnish a perfect transition from a bone in earliest forms with all the relations and appearance of the squamatan vomer to a bone in later (Triassic) forms with all the relations and appearance of the mammalian vomer.

On the positive side, White's studies of the reptilian heart have been incorporated into the work under review, vastly improving this work in comparison to standard comparative anatomy texts.

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be typewritten on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $16.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/8 inches (one column) or 9 1/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 12 5/8 inches). Line cuts are reduced 25 per cent in processing.

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

UNREVIEWED-UNEDITED COMMUNICATIONS

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions (see Advice to Authors).

Page charges are: $20 for a single page (148 lines of about 40 characters and spaces); $40 for the two-page maximum (300 lines). Include an allowance for the title and author's name and five lines for the address and received date. [Send a check for the proper amount with the manuscript, or if you prefer, we will bill you that amount for reprints.]

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

The Society was founded in 1958 as THE OHIO HERPETOLOGICAL SOCIETY. Following rapid growth of membership and expansion of operations, due largely to the originality and diversity of its publications program, the organization became the SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES in 1967.

Purpose. The SSAR encourages the acquisition of knowledge on amphibians and reptiles and the dissemination of scientific information on these animals. It encourages the conservation of wildlife in general, and of amphibians and reptiles in particular. A major effort is made to achieve closer cooperation and effective communication between amateur and professional herpetologists, so that they may work together in the common cause of furthering science.

Publications. The Society publishes the JOURNAL OF HERPETOLOGY, FACSIMILE REPRINTS IN HERPETOLOGY, and HERPETOLOGICAL REVIEW. Members receive all regular issues of these publications.

Membership & Subscriptions. Membership is open to anyone interested in amphibians and reptiles. Regular dues are $6. in the United States and Canada, $5. in other countries; Sustaining dues are $8., Contributing $15., and Life $100. Subscriptions for institutions and individuals are $10. All inquiries about membership or subscriptions should be addressed to the Secretary.

****

EDITORIAL

****

Again, this time due to mailing problems, this REVIEW has been made up before the membership has seen the last one.

However, the Editor is pleased to point out that this third issue is not completely authored by him, but has contributions from a variety of sources. There are Book Reviews by Brame and Kour, Conservation by Myers, Letters by Folkerts & Mount, Gordon, and Gilboa, and "Unreviewed" by Zug & Crombie. We appreciate all these as well as the end-prints by De Ran, and hope that they presage a new look in the contents of HR.

A rule-of-thumb is developing in regard to the placement of certain articles. Papers of general interest are run as articles, specific and specialized notes are run in "Herpetologists Record" or elsewhere if less than a column in length, as "Unreviewed-Unedited" if one to four columns. We still need articles and unusual photographs from the readership. -- HGD.

LETTERS

Reply to H. L. Freeman's (Herpetol. Rev. 2(1):3) comments on: A NEW SUBSPECIES OF THE TURTLE GRAPTEMYS NIGRINODA CAGLE. -- It is evident from Mr. Freeman's remarks on our recent paper that there are basic conceptual differences between his idea of subspecies and ours. Certain of his comments stem from this fact or from differences of opinion as to the purposes of taxa descriptions, and we welcome them as representative of a contrasting point of view. The majority of his other observations are based on unfounded assumptions, errors of logic and interpretation, and an apparent misunderstanding of certain evolutionary processes.

His statement that we "have failed to show that delticola has any clear-cut sets of characteristics which are peculiar to the region it inhabits" is untrue. The unique characteristics of the subspecies and the area in which they typify the populations were clearly stated. This set of characteristics does not occur in other populations of the species, as a perceptive perusal of the paper will reveal, and is therefore unique.

Mr. Freeman seems disturbed by the fact that the intergrades possess characteristics intermediate between the two subspecies. At least he dwells upon this fact in the fifth paragraph of his comment. Intergradation is the result of an intermixture of genes from two or more subspecies, and intermediacy of characteristics within the zone of intergradation is the expected result. The fact that this phenomenon occurs in G. nigrinoda is neither unusual nor surprising.

Freeman's idea that Figure 6, in which length-height relationships of the shell are plotted, "shows a north-south cline" is apparently based on a misinterpretation. Detection of clinal variation from such a figure would involve knowledge of the locality from which each specimen plotted was obtained. This information was not presented in the figure, which was included merely to show the tendency of the two subspecies to differ in this character. It appears that Mr. Freeman equates intermediacy of intergradient populations with clinal variation. Aside from the fact that clinal variation is often exemplified within a zone of intergradation, the phenomena are fundamentally different. Furthermore, the presence of clinal variation within a zone of intergradation neither indicates nor implies that this type of variation characterizes other populations of the species.

He further states that because the populations "are sympatric" and because of "extensive areas" of intergradation "it seems improbable" that subspecies have developed. Several conspicuous flaws are

evident in this kind of reasoning. First, sympatry, which implies genetic interchange in this case, in no way negates the fact that differential selective pressures can result in and maintain subspecifically distinct populations. Second, the extent of an area of intergradation is not directly related to the distinctness of the intergrading populations. If Mr. Freeman means that he would prefer that subspecies separated by extensive zones of intergradation not be recognized as such, it is certainly his right to hold this view. If, on the other hand, as it seems, he is implying that natural selection cannot result in such a pattern, then his ideas of evolutionary processes are, at best, unorthodox. As a point of fact, in this case the area of intergradation is not "many times greater than the range of the proposed subspecies," unless one erroneously calculates the latter merely by measuring the linear north-south distance from the upper to the lower end of the Mobile Bay drainage delta. The multiplicity of branching and anastomosing rivers, and the lakes interspersed among them, provide a total habitable area for delticola that is perhaps as great as that in the area of intergradation.

Our intent in this paper was to describe a subspecies, and in so doing to draw attention to the most obvious and significant kinds of variation occurring within the species and the geographical pattern that they form. The paper was not intended to be a comprehensive analysis of intraspecific variation, nor did we consider it necessary to adopt a didactic approach by belaboring obvious conclusions or dwelling on apparent inferences.

A comment on: THE ECONOMICS OF HERPETOLOGICAL PUBLICATION. By Herndon G. Dowling. 1970. Herpetol. Rev. 2(1): 4-5. --- Your interesting analysis of the economics of publication deserves further attention. Based on my experience as a journal editor, the estimates provided in Table 1 are, if anything, too low.

If one regards the reviewing mechanism as a teaching process, then the cost of acceptable vs. unacceptable manuscripts is quite the reverse of your figures. In six years of editing a broad spectrum biological journal, publishing 80-90 papers averaging 12 pages each annually, less than 5% of the manuscripts submitted required no revision of any sort. The bulk of editorial time was spent on the manuscripts intermediate between those clearly acceptable and those clearly unacceptable.

If you believe, as I do, that a rejected manuscript should be accompanied by a clear statement as to why it is unacceptable (the teaching process), then costs of rejecting at least equal, but generally exceed, those of accepting a manuscript.

In a journal published by a society depending on "hidden" subsidy, the membership ought to submit at least letter-perfect manuscripts. Even if an author cannot write clearly and concisely (improvement of clarity and conciseness requires the bulk of editorial time), he can read the manuscript one more time to correct spelling, typographical errors and check the literature citation section against the text, thus saving some of the "hidden" cost at the editorial level.

Further, it is important to point out that cost of primary publication represents only one data point in the total cost of printed scientific communication.

To costs of primary publication must be added those of secondary services (title announcement, indexing and abstracting services or journals), reprint exchange and library operations. For a generation brought up on the concept that scientific information was free, it comes as a rude awakening that each dollar paid in the form of dues is really an "information dollar" and covers only a fraction of the total cost of printed information transfer.

Finally, for the average American herpetologist, "hidden" and open subsidies at the primary level must be multiplied by 3 to obtain a better first approximation of printed communication. One wonders how long he will continue to pay his information dollars to minimally three societies when the same (or perhaps less) total money put into one organization could yield considerably more units of information/dollar than is now received.

A COMMENT ON THE STATE OF HERPETOLOGY: 1970. --- Herpetology is not a large field. However, its workers are not united in one professional society. Even in the United States there are three national herpetological societies, not counting such newcomer semi-popular societies as the INTERNATIONAL TURTLE AND TORTOISE SOCIETY and the INTERNATIONAL CROCODILIAN SOCIETY. Local organizations, such as the PHILADELPHIA HERPETOLOGICAL SOCIETY, CONNECTICUT HERPETOLOGICAL SOCIETY, the METROPOLITAN NEW YORK HERPETOLOGICAL SOCIETY and the LONG ISLAND HERPETOLOGICAL SOCIETY separate the total membership even more. Foreign societies in Africa, Europe, and Australia divide the field overseas as well. On the one hand, a profession is what its main professional organization does. On the other hand, the largest and oldest society, the AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, is so badly split (between ichthyologists and herpetologists) that it

is surely inadequate to meet the needs of either of the professions which it represents.

Although the ASIH is only one of the many academic organizations to which a herpetologist might or does belong, its strength must derive from its success in satisfying scholarly interests in our field.

On the national level, only SSAR and ITTS provide a "Letters" section as a forum for the exchange of ideas and information. Hopefully this will be available to a much larger audience than just members of this society. I feel that only a national society can and will lead to unification and meaningful direction. Even if one single society of herpetologists cannot come about just yet, there are some things we can and must do now. What are some urgent, new activities?

1. The official journals of the main organizations must publish more material that reflects the "relevant" or "practical" or "timely" activities of an increasing number of members. Our "image" is projected to the undergraduate and graduate students who glance at the journals while they are deciding (a) whether to enter the profession, and (b) what role to play inside or outside of it. Our most prestigious journal, COPEIA, fails to project the kind of image I am talking about. Its scope is becoming narrower and narrower on the one hand, while it is far too broad on the other. In other words, while the articles are narrow in scope and the journal suits itself to thinly spread and isolated interests, the journal reaches not the members of one profession, but of two -- ichthyologists as well as herpetologists. To continue to pretend that both halves of this journal interest all its readers is to ignore the status of two disciplines and, it seems to me, to ignore the needs of the majority of the members of two professions. Furthermore, the publication of COPEIA in its present form is wasteful, since every one of us is paying for something he doesn't need. We could save both time and money by publishing fascicles -- herpetology for the herpetologists, if you wish -- with each member getting as much of the journal as he needs. In addition, since COPEIA is still the major organ of our profession, it would make some sense to widen its scope in keeping with the role which it plays and which it ought to play.

2. With university facilities and cooperation, we should produce tapes and videotapes for both NET and other networks, frankly using all the imagination we insist we possess to excite the general public about our work. We should produce pilot programs as suggestions and models for small radio stations. We ought not to be afraid to publicize ourselves, perhaps even to undertake projects of popularization.

3. A scholarly organization must give emphatic sanction and repeated encouragement to legitimate activities that are now too often regarded as admirable and altruistic but not exactly "professional" and certainly not scholarly: editing our journals and catalogue accounts, activities in conservation or acting as advisors to amateur societies. Perhaps we need a number of symbols in membership directories to identify people who have experience or expertise in these special and often unrecognized kinds of activities.

4. Our other "image" is projected at business meetings held at annual meetings. Any important vote -- on resolutions and top officers -- should be held by mail ballot of the entire membership. It is generally agreed that younger members should have a significant place in a professional society. Few can agree on what that place might be. I think our role should be a more active one. Future members of our societies are and will be recruited from the lines of the amateur societies and undergraduate students. The youth's interest can be aroused by a good teacher or a good course. I am not proposing that the society deal with pedagogy, but it should set up guidelines and prepare materials for undergraduate courses.

All of this is a mere start, if even that -- a few desirables that might edge existing organizations closer to the actual wishes and legitimate interests of an increasing number of their members, with perhaps the by-product of enhancing their image in the eyes of justly cynical observers. No violation of academic freedom -- the freedom of the individual member to decide for himself how to use his time, talents, and energy -- is involved.

Let us dream together about a society which directs its primary efforts not only toward providing a forum for scholarly exchange at national and regional meetings and through appropriate publications, but also to meeting the needs and desires of the individual member through such things as information retrieval programs, perhaps an abstract project (the new policy of printing abstracts in HERPETOLOGICA is a positive one) and a voice in research, conservation and education. We should examine ourselves, as individuals and as members of the profession, from the point of view of the historian in some future generation who will be passing judgment upon us, our awareness, and our actions.

HERPETOLOGICAL* SOCIETIES
AMATEUR & PROFESSIONAL

H. G. Dowling & Itzchak Gilboa

If we assume that anyone who is interested in amphibians and reptiles is a herpetologist (and this is a common definition), then there must be thousands of such persons scattered about the globe. Even if we restrict the definition to those who are interested in the scientific study of these animals, there are many hundreds.

These "herpetologists" live in hundreds of different places and work on dozens of different aspects of the biology of amphibians and reptiles. The diverse interests are reflected in part by the thirty or more herpetological societies. Many of the physiologists, anatomists, cytologists, or ecologists that work on amphibians or reptiles, however, do not consider themselves herpetologists at all, and do not belong to any of the societies.

Nevertheless, these societies are extremely diverse in their interests and memberships, and most of them (including the "professional" societies) are open to anyone interested. Only a few (e.g., the African and Canadian societies) have restrictions on membership based on geography or age.

Some of the societies are made up mainly of people without professional training -- amateurs -- whereas others have a large percentage of trained zoologists. However, there is no sharp division between the memberships of amateur and professional societies. Many members of the ASIH, the oldest and largest of the "professional" societies, are high school or college students. Similarly, members of many "amateur" societies also belong to professional groups.

Under these conditions of overlapping memberships (and no one knows just how much overlap there is), it is surprising how little society-to-society contact there is. Only the SSAR, to our knowledge, has, "to achieve closer cooperation and understanding between amateur and professional herpetologists" as one of its stated objectives (Constitution, Art. 2, Sect. 3).

In pursuance of this objective, in June we sent out questionnaires to all of the herpetological societies and clubs that we could locate. A number of these have been filled-out and returned. Others were returned by the Post Office with "Address Unknown," or from some former member who stated that the organization was no longer in existence. At least sixteen such societies have disappeared in the last decade. Our list is still not complete, we are sure, but we publish it here (Table) as a step in finding out more about the societies, and to let SSAR members know something of the diverse offerings.

Some of the organizations are interested in only one group of animals (the Salamander Society, the Crocodilian Society); others are just local clubs where people get together for field trips, or to swap snakes or snake stories. Only a few (and this includes the "professional societies") have objectives that are explicitly defined -- and even fewer have specifically-outlined programs for attaining these objectives. Some do: state surveys, conservation, etc., but often "to increase knowledge of amphibians and reptiles" is the only statement.

The lack of specific objectives and programs has undoubtedly been a major factor in the decline and disappearance of some of the societies. Perhaps an even more prevalent factor is the fragile nature of the leadership in a small society. Often it is held together by an even smaller group of active individuals (sometimes a single individual). When such a person moves or becomes unavailable for some other reason, the society may die in spite of a reasonably-large membership.

We feel that the larger and more professional societies have much to offer the smaller ones in terms of leadership and organizational matters. On the other hand, the amateur societies often have led in conservation efforts and in educational programs -- aspects of herpetology often neglected by the professionals. We hope that the mere knowledge of one another's existence will provide some basis for an improvement in communication between these diverse groups.

The Eggomaniacs

Strange doings at Britain's Carr Mill Junior School. The school's headmaster, Douglas Appleton, was recently seen clambering to the top of the local fire department's tallest ladder. From this shaky perch, he began tossing eggs down onto the school's lawn, seventy feet below.

Had the good headmaster gone a bit dotty, like the aristocratic oddballs whose antics enliven P. G. Wodehouse novels? Not at all: In pelting the lawn with eggs, Mr. Appleton was merely reaffirming the British tradition that says amateurs sometimes have a thing or two to tell the experts.

The egg-pitching episode got under way, as *Time* magazine tells the story, when Headmaster Appleton was lecturing his science students on the remarkable shape and structure that give the fragile-looking egg its toughness and resiliency.

To bring his point home, Appleton tossed a number of eggs out a second-floor school window. When they landed on the greensward below, only a few broke open. Noting the "intense interest and wonderment" this demonstration produced among his students, Appleton tried an even bolder eggsperiment. He groped his way to the top of the fire ladder and dropped ten eggs. Seven of them landed unscathed in front of the astonished students, who had formed a semicircle at a respectful distance from the splashdown point.

Headmaster Appleton then got a helicopter pilot to drop eighteen eggs on the school's playing fields, from 150 feet up. No less than fifteen eggs rebounded from the turf stubbornly intact.

Soon word got out, and other British schools began to run torture tests on eggs. Realizing that the game was afoot, the British *Daily Mail* promptly paid a well-known cricket bowler to send eggs skimming across the green between two cricket posts, at ninety miles an hour. When the eggs stopped bouncing along the grass, six out of ten were still whole.

Nothing loath, the rival *Daily Express* chartered a light plane, which jettisoned five dozen eggs while flying low, at 150 miles an hour, across a field near the Carr Mill School. Again, fully 60 per cent of the hen-fruit survived the skip-bombing.

When the eggomania subsided, it left many a scientist muttering over his slide rule and revising his notions about the common egg's uncommon durability. The nation-wide egg craze also left in its wake hundreds, perhaps thousands, of British youngsters who, their interest awakened by the episode, may someday become serious amateur scientists or even professionals.

Britain has, of course, long been a land aswarm with Appleton-style amateurs. Working alone or through amateur societies, they grind telescope mirrors, peer through microscopes, bone up on exotic languages, and in general serve the professional communities as a friendly auxiliary force.

Occasionally, gifted amateurs even outdo the professionals.

The classic case is that of Michael Ventris, a British architect and language hobbyist. In 1956, when he was in his mid-thirties, Ventris staggered the world's archeologists by translating hitherto undecipherable inscriptions left by the ancient Minoans. "Some of us," a professional archeologist commented dryly, "have derived great pleasure from the fact that the deciphering was done by an amateur, not a member of the union at all."

By coptrast, amateur groups in the United States are on the anemic side, and our amateurs generally work in the shadows. How many Americans have heard of Grote Reber, the Wheaton, Illinois, amateur who in 1937 used odds and ends to build the world's first working radio telescope? Yet a teenager, Kaoru Ikeya, became a minor national hero in Japan when, in 1963, he discovered a major new comet, using a homemade telescope built at a cost of $20.

Why doesn't the United States have a vigorous amateur movement in the humanities, social sciences, and natural sciences? Perhaps because amateurs think professionals have no use for them, and professionals hardly know that there *are* any amateurs.

Yet, Yale biologist Edmund Sinnott said a decade ago that science alone needs ten million amateurs, to do team work under the direction of pros and to serve as a human bridge between scientists and laymen. Astronomers have long depended heavily on reports from thousands of organized volunteers who monitor stars, meteors, fireballs, and the planets. Other amateurs do valuable work in weather-watching, archeology, and oceanography.

Overall, though, our amateur movement remains puerile and lackluster alongside Britain's. In a time when people are bewailing the alienation of youth and of blue-collar workers, it is unfortunate that the United States does not have millions of enthusiastic amateurs working with top men in all the professions and disciplines. Such a movement might well, in its own small way, help knit together our badly raveled society.

What would happen if the government or a major foundation encouraged the emergence of a wide-ranging U.S. amateur movement? The very idea of moon-watchers in the slums and amateur archeologists among the grape-pickers will strike some people as hilariously visionary. But if an ordinary egg can (as Headmaster Appleton has shown us) survive a free fall from 150 feet up, what miracles may we not hope for from sentient human beings?

AMPHIBIANS AND REPTILES PROTECTED IN PANAMA

The Republic of Panama provided nominal protection for one kind of amphibian and two species of reptiles, among other animals, in a decree dated January 30, 1967. The tortuga verde, or green sea turtle (Chelonia mydas), and the rana dorada, or Panamanian golden frog (Atelopus zeteki), are to receive absolute protection from slaughter or capture, with fines equivalent to U.S. $50.00 and $5.00, respectively, for each infraction. The iguana (Iguana iguana), which is eaten by most ethnic groups in Panama, can no longer be hunted for commercial purposes and cannot be taken even for personal use during the period of December 1 to May 1, which corresponds to the dry season in most parts of the republic. This is the period when iguanas nest and when populations of these large lizards normally receive maximum pressure from hunters. A protein-starved Indian, or a slash-and-burn farmer with a family to feed, is unlikely to pay much attention to the legal protection afforded green turtles and iguanas, even if he understood the rationale and need for such laws. Nevertheless, the establishment in Panama of a National Commission for the Protection of Wildlife is an important step for the conservation of the natural resources of that country.

The golden frog, which is perhaps best considered a subspecies of Atelopus varius, is in particular need of protection. It seems to be confined to the volcanic uplift of the El Valle-Cerro Campana region, part of which is a resort area, and the living frogs are bought as terrarium pets by tourists from Panama City and the Canal Zone. The golden frog's appeal stems not only from its bright color, but also from its being associated in the public mind with the pre-Columbian frogs of real gold that are still being dug from Indian graves in western Panama. The golden frog has been almost extirpated in the crater of El Valle, the type locality, but the real threat is not so much from the relatively small tourist trade as from commercial exploitation of a larger nature --- I have learned of one recent shipment to the United States of approximately 600 specimens, in clear violation of the Panamanian law. Matters should be helped by a new U.S. Federal law, effective August 3, 1970, that prohibits importation of animals from countries where they are protected.

Crocodilians are not mentioned in the Panamanian decree, and neither of the two native species (Crocodylus acutus and Caiman crocodilus fuscus) is on the new "United States List of Endangered Foreign Fish and Wildlife." However, there is a sort of crocodilian preserve in the Territory of San Blas and part of adjacent Darien Province, where at least some groups of Cuna Indians will impose their own fines for the killing of such religiously important animals. Although not seriously endangered in Panama at this time, the crocodile can nonetheless use such protection, as it occurs principally in the larger bodies of water and nowhere seems really abundant. Fortunately there is no large-scale hide industry in Panama, and a flurry of recent laws in the United States and elsewhere makes it unlikely that one will develop. Caimans are abundant in Panama and are hardly likely to be endangered in the foreseeable future, unless the farmers and Indians discover that they are overlooking a tasty source of protein.

AVISO AL PUBLICO

EL DECRETO Nº 23 DE 30 DE ENERO DE 1967. SOBRE PROTECCION A LA FAUNA SILVESTRE. EN SU ARTICULO 2º. CON EL PROPOSITO DE PROTEGER PARCIALMENTE A LA IGUANA. PROHIBE SU CAZA CON FINES COMERCIALES Y ESTABLECE UNA EPOCA DE VEDA A PARTIR DEL 1º DE DICIEMBRE DE CADA AÑO HASTA EL 1º DE MAYO DEL AÑO SIGUIENTE.

EN CONSECUENCIA. LOS ALCALDES CORREGIDORES. REGIDORES. COMISARIOS. GUARDIA NACIONAL Y LOS MIEMBROS DE LAS COMISIONES DE PROTECCION DE LA FAUNA SILVESTRE. PROCEDERAN A DECOMISAR TODAS LAS IGUANAS VIVAS EN VENTA. SEA CUALQUIERA EL LUGAR DONDE SE ENCUEN_ TRAN. DURANTE ESTA EPOCA.

COMISION NACIONAL DE PROTECCION DE LA FAUNA SILVESTRE.

Panamanian poster that prohibits hunting of iguanas for commercial reasons and which imposes a closed season from December 1 to May 1.

CURRENT HERPETOLOGICAL TITLES, XI: 1969 - 1970

Herpetological Information Search Systems
American Museum of Natural History
New York, N. Y. 10024

In the last two and a half years we brought to your attention some 11,000 current titles in the pages of this journal.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts-Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses especially.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of some interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any paper that is concerned with a member of a Recent order of amphibians or reptiles.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This eleventh list contains titles of books and articles that have come to our attention during the period 1 May 1970 through 20 July 1970. The list is divided into two separate, alphabetically arranged sections: one for titles published in 1969, and one for titles published in 1970.

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and T. Shaman. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. Dr. Robert W. Winter provided us with translations of titles, abstracts and papersz from Slavic languages. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

Members of the Herpetology Department and the Library staff of the Museum have continued to aid our efforts. No commercial computer service yet offers all of the facilities that we need, however, and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 21 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).

*H*ERPETOLOGICAL
*I*NFORMATION

JOURNALS INCLUDED

Listed below are the 393 different journals (several issues of some) in which articles relating to amphibians and reptiles were found during this quarter. This list is intended, not only as an indicator of the highly scattered nature of articles pertaining to these animals, but as a warning. It is unlikely that any one library will have all these journals. None of the large medical, biological or biochemical abstracting services covers all of these journals nor does Zoological Record. How can one find them? Can we ignore them? If someone thinks that some at least can be ignored, which ones? If you have any ideas let us know.

BOOK REVIEW

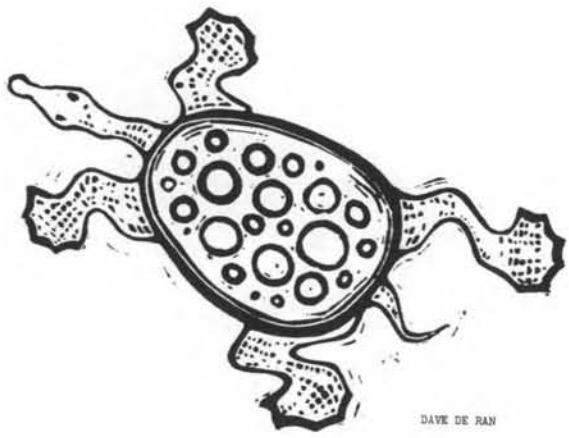
****

THE NEW FIELD BOOK OF REPTILES AND AMPHIBIANS. By Doris M. Cochran and Coleman J. Goin. 1970. G. P. Putnam's Sons, New York. xxii + 359 p., 100 black and white figs., 96 color photographs in 16 plates (6 per plate), and 5 unnumbered drawings of anatomical parts of the salamander, frog, turtle, lizard, and snake. $5.95.

This long-awaited field guide has finally appeared and will undoubtedly be very popular amongst professional and amateur herpetologists alike. The organization of the book is simple, beginning with a one-page preface and two-page introduction, and followed by the text, which consists of six main groupings (= orders or suborders): (1) Sirens and Salamanders; (2) Frogs and Toads; (3) Crocodilians, Family Crocodylidae; (4) Turtles; (5) Lizards; and (6) Snakes, in that order. At the introduction for each group, there is a brief discussion of the order or suborder, followed by the family, genus, species, and subspecies accounts, arranged generally in a primitive to advanced sequence. The species and subspecies accounts vary from 2 to 37 lines in length and the following description is an example:

> "Limestone Salamander, Hydromantes brunus (Figure 12).
>
> This species has a longer tail, longer legs, and longer toes than the Mount Lyell Salamander. The tips of the toes overlap when the limbs are adpressed by 1 1/2 intercostal folds. Adults are uniformly brown above, pale below, with yellow on the underside of the tail. Young are pale yellowish-green above. This form is known from the lower Merced Canyon in Mariposa County, California, at altitudes of 1,200 to 2,500 feet."

The book concludes with a list of Selected References and the Index to both scientific and common names combined.



The untimely death of the senior author two years ago and the recent illness of the junior author, probably slowed the appearance of this work. The unfortunate "long term in press" apparently prevented the inclusion of forms described over the past three years as well as changes in classification and nomenclature during this period. For instance, the old classification of Campbell (1931) for Batrachoseps is followed. This was altered considerably by Brame and Murray (1968), including the description of three new forms. Also, the photograph of a Batrachoseps from San Diego County (Fig. 5) is labeled, "California Slender Salamander, Batrachoseps attenuatus," whereas it is clearly B. major, the Garden Slender Salamander. Further, Hyla cadaverina was shown to be an older name for H. californae by Duellman (1968) and species names for Syrrhophus have been revised by Lynch (1970).

Some forms were included that should not have been, viz. subspecies of Leurognathus, as Martof, who had originally described three of the races, later sunk them all in 1962. Conversely, several species are not included that have been described, elevated to species rank from synonymy, or found to occur within the continental USA well in advance of the final preparations of the book, viz. Typhlomolge tridentifera (Mitchell and Reddell, 1965), Ambystoma platineum and A. tremblayi (Uzzell, Copeia, 1964 (2): 257-300), Cnemidophorus flagellicaudus and C. sonorae, described by Lowe and Wright (1964), Rhinophrynus dorsalis reported by James (1966) to occur in southern Texas, and Tantilla oolitica and T. relicta described by Telford (1966).

One can't help comparing this work to the two Peterson Field Guides: "A Field Guide to Reptiles and Amphibians" - Eastern USA by R. Conant (1958) and "A Field Guide to Western Reptiles and Amphibians" by R. C. Stebbins (1966). The Peterson Field Guides contain much more detailed information, illustrations of nearly every species, thorough maps, and detailed descriptions of eachz species, and thus these books are far more useful to the professional or advanced amateur herpetologist. The New Field Book of Reptiles and Amphibians will be of more interest to the layman or beginning amateur herpetologist. Despite its drawbacks, everyone who calls himself a herpetologist should have a copy in his library.

BOOK REVIEW

THE FROG. By T. A. G. Wells. 1968. [Reprint, 1964 Ed., Heineman Ltd.] Dover Publications, Inc., New York. viii + 44 p., 16 drawings. Paperbound. $1.35.

This manual is a dissection guide for the European frog, Rana temporaria. It has been designed to aid British students in studying for standardized examinations. Included are diagrams and detailed descriptions of the skeleton, vascular system, and nervous system. There are briefer sections on the musculature, visceral organs, external features, and parasites.

With the trend away from dissection for its own sake in American schools (and even Scottish ones), it is unlikely that this book will find a large market here. Many of the drawings are not as realistic as those generally available, and the carry-over from European to the American frogs most often used for dissection here is not complete (the girdles and skull have the same basic elements, but their appearance differs appreciably).

It is likely that this guide would be most helpful to high school and college teachers as a quick reference to frog anatomy. Useful features are the glossary of Greek and Latin roots and the brief exercises on observing living frogs and frog parasites.

MODIFICATIONS OF THE TAYLOR ENZYME METHOD OF CLEARING AND STAINING FOR AMPHIBIANS AND REPTILES

George R. Zug and Ronald I. Crombie

Taylor (1967) developed his clearing and staining method primarily for fish. During the developmental stages, he tested his method on a number of specimens in the herpetological collection of the U.S. National Museum of Natural History and found that although the results were satisfactory they were not ideal. We have recently discovered a number of modifications which greatly improve the quality of cleared and stained amphibians and reptiles. The following steps correspond numerically to those in "The Methods" section of Taylor's article (1967).

1. Specimens may be killed either with a chlorotone solution (amphibians) or Nembutal (reptiles). Specimens are preserved immediately upon death by injecting buffered formalin into the body cavity. We used the concentrated formaldehyde solution (40 per cent formaldehyde) as prepared by the manufacturer. This solution is not diluted, only buffered, i.e., approximately a half a teaspoon of sodium borate per quart of formalin. Although this produces hard and brittle specimens, they are ideal for clearing and staining. Following preservation, the specimens are positioned for fixation in air-tight trays containing a shallow layer of formalin and covered with formalin-dampened paper towels. The limbs and digits should be carefully positioned to facilitate the eventual examination of the specimens. The specimens are allowed to fix for 12 to 24 hours and then transferred to and stored in either concentrated or 4 per cent formalin. We have observed no differences in the final results owing to the concentration of the formalin. To date, we have stored no specimens more than a month.

2. Specimens are washed in several changes of water for two to three days. Specimens are removed from the water and skinned. Since the manner of preservation produces brittle specimens, extreme care is required in skinning to avoid dismembering the appendages. The eyes should not be removed since there are sclerotic ossicles in most reptiles and their pigment is an aid in timing of a following step. The specimens are eviscerated and returned to water for several hours.

3. Reptiles and amphibians have been bleached in a 20 per cent stock hydrogen peroxide and 80 per cent stock potassium hydroxide solution with satisfactory results. The bleaching, buffer, and enzymatic solutions are all exposed to a 75 watt lamp. The bleaching solution is exposed directly to the lamp and maintains a temperature of approximately 30 C.; the enzyme and buffer solutions are at 25-26 C. owing to indirect exposure.

The size of the specimen and the thickness of the muscle masses determine the amount of time in the bleaching solution. The time range is from one day for small anurans, e.g., Limnaeoedus ocularis, to two weeks for larger amphibians and reptiles, e.g., Bufo terrestris or hatchling Kinosternon. Our suggested bleaching time greatly exceeds that of Taylor, since we use this step for clearing as well as for removal of the pigment. Specimens are removed from the bleaching solution when most of the thinner muscle sheets have become transparent, the thicker muscle masses have become translucent, and the eyeballs have lost all their pigmentation.

4. The specimens are placed in a buffer solution. Small, transparent specimens may be transferred directly to the alizarin (step 7) after a short rinse in water.

5. and 6. The specimens are transferred to an enzymatic solution. The specimens should remain in this solution for no more than two or three days and generally much less. If the specimens are exposed for longer periods of time, there is a high probability that phalanges will drop off, even after they have been stored in glycerine. In most instances, a maximum of eight hours is sufficient. With larger specimens, it is advisable to follow this step with a five to six hour wash in 65 per cent ethyl alcohol. This wash has the advantage of halting enzymatic activity and simultaneously hardening the remaining tissue.

7. The specimens are placed in a solution of alizarin red S and stock potassium hydroxide. Penetration of the dye through thick muscle masses is insured by using a blunt probe to separate the muscles. Specimens can usually be removed from this solution after a day; however, inspection of intensity of staining is the best indicator. The alizarin solution should be renewed frequently for good results. As soon as there is a noticeable decrease in the intensity of the stained bones, prepare a new solution.

8. and 9. These steps are omitted, since skinning and evisceration were performed in step 2.

10. and 11. These are optional steps, and we have had no cause to use them.

12. The specimens are transferred to a 40 per cent glycerine and a 60 per cent ethyl alcohol (65 per cent) solution. Initially the specimens will rest on the surface. When they have sunk (approximately 2 to 3 days), they have equilibrated and should be transferred to a 70 per cent glycerine and 30 per cent alcohol solution. After several more days, they can be placed in 100 per cent glycerine. Please note that we have substituted 65 per cent alcohol for distilled water in the glycerine series.

This substitution has resulted in firmer specimens.

SUMMARY

Five modifications of the Taylor enzyme method of clearing and staining are proposed: 1) Preserve the specimens in 40 per cent formalin; 2) skin and eviscerate before bleaching; 3) increase the time of immersion in bleaching solution; 4) decrease the time of immersion in enzymatic solution; 5) replace distilled water with 65 per cent ethyl alcohol in the glycerine series. All these modifications produce a very transparent specimen with a decreased likelihood of specimen disarticulation, particularly of manus and pes.

ACKNOWLEDGEMENTS

We wish to thank Drs. W. R. Taylor and J. A. Peters for their criticism of the manuscript. This work has been supported by a Smithsonian Research Foundation grant to G. R. Zug.

HERPETOLOGISTS RECORD

****

HEMIPENIS MORPHOLOGY OF CORALLUS. -- In reading Garth Underwood's "A Contribution to the Classification of Snakes" (1967, PUBL BRIT MUS NAT HIST (653)), I was surprised to encounter the following statements: "Boulenger points out that snakes with hind-limb vestiges do not have spiny hemipenes (this is not quite true of Corallus caninus)" (p. 27), and, "The hemipenis /of Corallus caninus/ is bilobed and the sulcus forked, there are a few spines at the base" (p. 79).

Boids otherwise are not known to have spinose hemipenes, and the specimens of C. caninus at hand (Figure) showed none. I

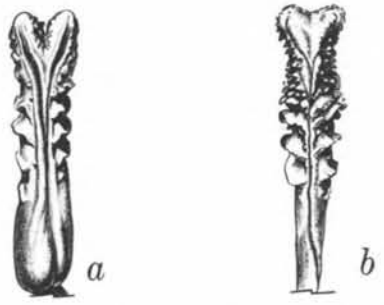

FIGURE. Everted hemipenes of two species of the boid genus Corallus: A. Corallus caninus, B. Corallus enydris. Note the absence of spines, and the presence of flounces and papillae.

wrote Dr. Underwood about this and he kindly reexamined the specimen on which his statements were based. He wrote (in litt., 2aug69), "Under low power there are what look and feel like spines in about the right place. However, under high power their shapes are irregular and I can only conclude that they are some kind of calcareous concretion associated with the manner of preservation or storage, the specimen is old."

Thus, Corallus caninus, like other members of its genus and other genera of the family Boidae, has a spineless hemipenis. The only ornamentation is made up of transverse flounces and irregular papillae. -- H. G. Dowling, AMER MUS NAT HIST, New York, N. Y. 10024. RELATIONSHIPS OF THE ASIAN SUNBEAM SNAKE, XENOPELTIS UNICOLOR

Herndon G. Dowling & Frances W. Gibson

The recent discovery that Xenopeltis unicolor has a typically boid chromosome complement (Cole & Dowling, 1970) adds another dimension to an analysis of its relationships. The same specimen that provided the karyotype (AMNH 104370) also offered the first opportunity of obtaining an everted hemipenis preparation. The features of the hemipenis, too, give added information on Xenopeltis relationships; these are presented here.

BACKGROUND

Xenopeltis unicolor Reinwardt (1827: 564) was early recognized as a misfit in ordinary snake classification. Bonaparte (1845) placed it in a monotypic taxon of family rank, and this separation has been recognized by almost all subsequent workers (Cope, 1864: 230; Boulenger, 1893: 167; Underwood, 1967: 65; Oldham et al, 1970: 88). Only Romer, Hoge, and Bellairs have made different taxonomic allocations.

Romer (1956: 570) placed Xenopeltis as a monotypic subfamily in his expanded Family Aniliidae (which also included the Uropeltidae). Bellairs (1970: 525) followed this allocation. Hoge (1964), on the other hand, pointed out the presence of a coronoid bone on the lower jaw of Xenopeltis -- a bone that all previous workers had claimed was absent -- and on this basis placed it in a monotypic Subfamily Xenopeltinae of the Family Boidae. This paper appears to be unknown to subsequent authors.

One other important reference to the relationships of Xenopeltis is that of Haas (1955), though he took no formal action on its classification.

FAMILIAL ALLOCATION

Xenopeltis possesses a number of primitive features. The presence of teeth on the premaxillary (found otherwise only in Anilius and some pythons) and the large left lung (about half the size of the right) have been known for many years. The presence of the coronoid bone, first pointed out by Hoge (1964), has been confirmed by us from a skull in this Museum (AMNH 29969). The apparent division of the bone as figured by Hoge, however, is probably merely a break in the specimen; the coronoids on the Museum specimen are entire.

Due probably to its burrowing habits, Xenopeltis has a skull which is stoutly constructed and possesses short supratemporal and quadrate bones. The premaxillary is in contact with the maxillaries. However, this snake does not show the extreme reduction of ventral scutes and supratemporal bone and suturing of jawbones that are characteristic of the burrowing snakes of the Aniliidae and Uropeltidae.

Xenopeltis was separated from the boids mainly on the basis of the reported lack of a coronoid bone, the reported intercalation of the supratemporal in the braincase, and the absence of pelvic elements. Of these features, only the last proves to be correct. When the feature of a typical boid karyotype is added to the summary of its true morphology, allocation of Xenopeltis to the Boidae seems reasonable in spite of the absence of pelvic elements (pelvic elements are of irregular occurrence in other families, vide List, 1966). Further, Xenopeltis shows other resemblances to at least one member of that family (see below).

SUBFAMILIAL ALLOCATION

Haas (1955) suggested a relationship between Xenopeltis and the American "burrowing python" Loxocemus, on the basis of similarities in jaw musculature. However, probably because of the lack of zoogeographic correlation and the erroneous information in the literature on the skeletal morphology of Xenopeltis, he did not suggest any change in the then-current arrangement of these snakes in separate families. Nor have other workers followed up this lead.

It is of interest, therefore, that the hemipenis morphology of Xenopeltis also suggests close relationship with Loxocemus. The hemipenis of Xenopeltis is flounced and bilobed, with a bifurcate sulcus, as is that of most boids. However, it also has unornamented apical disks (Fig. 1a). The

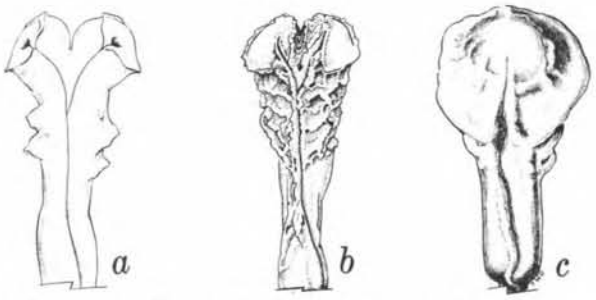

FIGURE 1. Everted hemipenes of some "burrowing pythons": a. Xenopeltis unicolor, b. Loxocemus bicolor, c. Calabaria reinhardtii. The hemipenis of Calabaria, a snake that is tentatively associated with the other two, is unique, but resembles a much-expanded disk.

only other snake known to have a hemipenis with these characteristics is Loxocemus (Fig. 1b). Though not identical, the hemipenes of these two genera are similar in all respects.

Most Old World pythons, which might have been expected to show resemblance to Xenopeltis on zoogeographic grounds, have hemipenes with a papilla at the apex of each lobe (Fig. 2). This feature has proven to be characteristic of all of the species of Python as yet examined (P. molurus, P.

regius, P. reticulatus), as well as of the allied genera Liasis and Aspidites.

We do not wish to overstate the usefulness of the hemipenis in the establishment of intergeneric relationships. However, in the absence of any clear indication of relationship in other directions, we believe that the disked hemipenes of Xenopeltis and Loxocemus support Haas's suggestion of close relationship between these genera, and their separation from those genera more closely

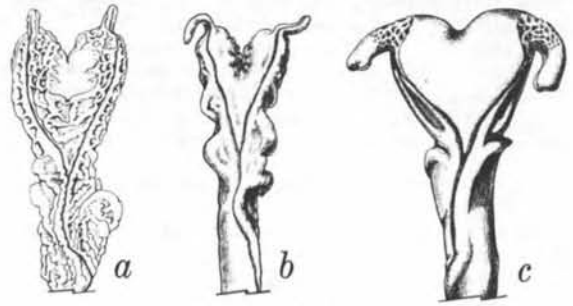

FIGURE 2. Everted hemipenes of Python and some related genera: a. Aspidites melanocephalus, b. Liasis amethistinus, c. Python molurus. The apical awns are also found in Bothrochilus and other species of Python.

related to Python. We recommend, therefore, that Loxocemus and Xenopeltis be placed in a separate subfamily of the Boidae.

Another "burrowing python" of unknown relationships is Calabaria of West Africa. It proves to have a unique hemipenis, with a single sulcus (the only one known in the Boidae) and a strange, mushroom-shaped apex (Fig. 1c). No similar organ is known in the Serpentes. The hemipenis is not particularly Xenopeltis-like, but is even less Python-like. Such an organ could have evolved from a disked hemipenis, however. Rather than leaving Calabaria in some kind of limbo, we tentatively associate it with Xenopeltis and Loxocemus, in spite of reported differences in dentition and skeletal morphology, and in spite of its further fragmentation of the range of the Xenopeltinae.

SUMMARY

The taxonomic arrangement suggested here is as follows:

Suborder SERPENTES

Superfamily BOOIDEA

Family BOIDAE

Subfamily Xenopeltinae

The included genera are Xenopeltis Reinwardt (1827: 564), Loxocemus Cope (1861: 76), and ?Calabaria Gray (1858: 154).

ACKNOWLEDGMENTS. We wish to thank Charles W. Myers and Itzchak Gilboa, of this Department, for their criticism of the manuscript.

A LIST OF HERPETOLOGICAL TYPE LISTS

H. G. Dowling, I. Gilboa, & R. G. Zweifel

****

"Committee Number 2" of the International Council of Museums began to prepare a universal catalogue of type specimens in zoology and paleontology in 1958. It was soon apparent that this was an impossible task and in 1965 the Committee's program was modified to provide a list of the catalogues of types that had already been published by various museums. This list was published in 1968? [we do not have a full citation] and contained 18 titles under "Amphibia, Reptilia," plus some additional titles under "Zoology (General)."

This Department has maintained a card file on papers which relate to herpetological type specimens for some years. We have updated this list and publish here 53 titles pertinent to this subject. We would appreciate readers bringing any additional papers to our attention.

MEETINGS AND SOCIETIES

****

CALENDAR 1970

26-31 December....AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, Annual Meeting, Chicago.

26-30 December....VERTEBRATE MORPHOLOGY DIVISION, AMERICAN SOCIETY OF ZOOLOGISTS, Annual Meeting (with AAAS).

28-30 December....HERPETOLOGISTS LEAGUE, Annual Meeting (with AAAS).

CALENDAR 1971

15-19 June....AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, Annual Meeting, Los Angeles.

****

The WILDLIFE PRESERVATION SOCIETY (Stevenage, England) announced that it had saved the lives of more than 1,000 toads in one week by redirecting traffic on a main road where the toads were crossing from one spawning pond to another (N. Y. Times, 5may70). [Incidentally, the IDAHO FISH AND GAME DEPARTMENT classifies bullfrogs as "fish."]

The AUSTRALIAN SOCIETY OF HERPETOLOGISTS' NEWSLETTER (11) carries numerous items of interest, including news of the research efforts of various members. The Society objected to our listing of such titles previously, so we refer you to their publication.

****

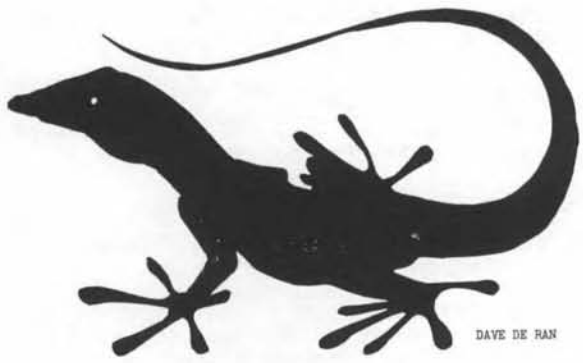
INDIVIDUALS AND INSTITUTIONS

****

J. A. HOLMAN (Michigan State U.) is studying (among other things) an Upper Miocene herpetofauna from the Wood Mountain Formation of Saskatchewan.

THE THIRD DRESDEN TERRARIUM SHOW (July & August) had a number of herpetological exhibits, including some 25 species of venomous snakes (AQUAR TERRAR 17(4): 124).

SCOTTISH SEA MONSTERS are in the news again this tourist season, with an ecologist suggesting that the Loch Ness Monster may have been killed by pollution (an idea shrilly objected to by locals). Fortunately, however, a competing monster named Morag has been reported from nearby Loch Morar.



The BUREAU OF SPORT FISHERIES AND WILDLIFE reported that among the 78,045,922 live animals imported into the United States last year (almost 74 million fishes) were 339,489 amphibians and 1,393,970 reptiles. The ENDANGERED SPECIES CONSERVATION ACT, which (among other things) makes the importation of animals protected in their country of origin illegal, goes into effect on 3 August 1970.

RUTGERS UNIVERSITY: JAMES D. ANDERSON is teaching ecology, after a year's sabbatical working on various Ambystoma projects. SAMUEL B. McDOWELL is visiting the British Museum to look at sea snakes.

UNIVERSITY OF RHODE ISLAND: VICTOR H. HUTCHISON will move to the University of Oklahoma as Chairman of the Zoology Department. C. ROBERT SHOOP will take over Hutchison's post as Director of URI's INSTITUTE OF ENVIRONMENTAL BIOLOGY. ROBERT W. GUIMOND (Ph.D., 1970) will stay at URI for a year as instructor in zoology. JAMES D. LAZELL received his Ph.D. in June (anoline lizards of the Lesser Antilles). TERRY E. GRAHAM has taken a position in the Biology Department of Worcester State College, Worcester, Mass.

AMERICAN MUSEUM OF NATURAL HISTORY: C. J. COLE is in Mexico for about three months, collecting lizard chromosomes. JANIS A. ROZE goes on the full-time staff of the City College of New York. C. M. BOGERT (Curator Emeritus) reports that he has obtained two more specimens of his new boa, Exiliboa placata, in Oaxaca.

ADVICE TO AUTHORS

Herpetological Review publishes feature articles that pertain to amphibians and reptiles, the people who study them, and the relevant societies and institutions. It is not intended as an outlet for reporting the results of research on these animals (but see "Unreviewed-Unedited"). Articles describing (and/or photographs illustrating) rarities, expeditions, laboratories, societies, museums, and historical articles that pertain to herpetological study are especially welcome. We would also appreciate news for the various Departments.

FORMAT. Manuscripts should be typewritten on white bond paper. All material, including legends for figures and literature cited, is to be double-spaced. Scientific names of genera and species are underlined. Titles should indicate clearly the subject and animal group(s) included. Use standard abbreviations for journals. See the special instructions for "Unreviewed-Unedited Communications."

The following publications will be of assistance in the preparation of manuscripts:

Catalogue of American Amphibians and Reptiles (Herpetological Catalogue Committee, American Museum of Natural History, New York, N. Y. 10024). $16.

Common names for North American amphibians and reptiles (Copeia 1956(3):172-185).

Scientific Writing for Graduate Students, by F. Peter Woodford (Rockefeller University Press, New York, N.Y. 10021). $5.75.

Biological Abstracts List of Serials with Title Abbreviations (BioSciences Information Service, 2100 Arch Street, Philadelphia, Pennsylvania 19103). $10.

Style Manual for Biological Journals (American Institute of Biological Sciences, 3900 Wisconsin Avenue, NW, Washington, D.C. 20016). $3.00.

ILLUSTRATIONS. The author's name, abbreviated title of the manuscript, figure number, and the notation "Top" should be penciled lightly on the back of all illustrations. Number the captions consecutively and list these on a separate page.

Line-cuts are photo-offset directly with the text, and should have widths of 4 3/8 inches (one column) or 9 1/4 inches (two columns). Each inch of illustration length equals six lines of text (full page copy length is 12 5/8 inches). Line cuts are reduced 25 per cent in processing.

Photographs and drawings reproduced by half-tone plates are handled separately but should be planned for one-column or two-column reproduction.

A publication that will be found helpful in planning and producing adequate illustrations is:

A Handbook of Biological Illustration, by Frances W. Zweifel (University of Chicago Press, Chicago, Illinois). $1.95.

PROOFS AND SEPARATES. Proofs will be sent to each contributor. Author's separates are made available at reasonable rates, and may be ordered when proof is returned.

UNREVIEWED-UNEDITED COMMUNICATIONS

"Unreviewed-Unedited Communications" is intended for single-subject notes of original observations, preliminary reports, or new ideas on amphibians and reptiles that can be presented in a maximum of two printed pages. Notes on anatomy, behavior, embryology, geographic distribution, physiology, or similar subjects are acceptable. It may be used also for speculations on phylogeny or comments on nomenclature. It is NOT to be used for the description of new taxa.

Because the reviewing and editing processes typical of journal publication are omitted, this section offers a rapid, inexpensive, and relatively-uncensored route of publication. Submission-time to publication-time is two to three months.

These articles will enter the scientific literature on amphibians and reptiles. Authors should list three to six index terms that indicate the limits of subject-material, geography, and included taxa.

The absence of the usual checking mechanisms of the ordinary publication process makes it doubly important that the author write clearly and that he review the manuscript carefully for typographical errors before submitting it. In no other form of publication is the author so clearly responsible for the content and presentation of his work.

This section is supported entirely by its authors and their sponsors. Page charges pay the costs of publication, distribution, and 100 author's reprints. Illustrations may be included but must be reduced to proper dimensions (see Advice to Authors).

Page charges are: $20 for a single page (148 lines of about 40 characters and spaces); $40 for the two-page maximum (300 lines). Include an allowance for the title and author's name and five lines for the address and received date. [Send a check for the proper amount with the manuscript, or if you prefer, we will bill you that amount for reprints.]

BIOLOGY OF REPTILIA

General Editor: CARL GANS,
State University of New York, Buffalo, New York

This multi-volume treatise presents a comprehensive view of the class *Reptilia*. The work is divided into the sub-areas of morphology, embryology and physiology, and behavior and ecology. Volume 1 introduces the general area of morphology, beginning with a statement of the pre-history of the major groups of recent reptiles and going on to deal with bone as a tissue, and with such osseous elements as epiphyses and sesamoids, the turtle shell, the vertebral column and ribs, and the reptilian dentition.

VOLUME 1: MORPHOLOGY A—co-edited by A. d'A. BELLAIRS, St. Mary's Hospital Medical School, London, England, and THOMAS PARSONS, University of Toronto, Ontario, Canada

Contents: ROBERT L. CARROLL: **Origin of Reptiles:** Introduction. The Ancestry of Living Reptiles. Lower Permian and Carboniferous Reptiles. Paleozoic Amphibians and the Origin of Reptiles. The Environment of Early Reptiles. Definition of a Reptile. Summary. References. DONALD H. ENLOW: **The Bones of Reptiles:** Introduction. Early History. Types of Reptilian Bone Tissue. Patterns of Bone Structure in Modern Reptiles. Significance of Cortical Stratification. Evolution of Reptilian Bone. Bibliography and References. R. WHEELER HAINES: **Epiphyses and Sesamoids:** Introduction. Epiphyses and Related Structures. Sesamoids. References. A. G. EDMUND: **Dentition:** Introduction. Dental Morphology. Dental Development. The Egg Tooth and Egg Caruncle. Description of Fossil and Recent Dentition. References. ROBERT HOFFSTETTER and JEAN-PIERRE GASC: **Vertebrae and Ribs of Modern Reptiles:** Introduction. General Morphological Features of Reptilian Vertebrae and Ribs. Structural Patterns in the Living Order of Reptiles. Conclusions. References. RAINER ZANGERL: **The Turtle Shell:** Introduction. Anatomy of the Turtle Shell. Comparative Morphology of the Turtle Shell. Phylogenetic History of the Turtle Shell. Summary. References. Author Index-Subject Index.

1969, 373 pp., $13.00

VOLUME 2: MORPHOLOGY B—edited by CARL GANS.
Co-edited by THOMAS S. PARSONS

CONTENTS: GARTH UNDERWOOD: **The Eye**: Introduction. Embryology. Lacertilia and Amphisbaenia. Snakes. Rhynchocephalia. Testudines. Crocodilia. Scleral Ossicles of Extinct Forms. General Discussion. Systematic Discussions. Acknowledgements. References. THOMAS S. PARSONS: **The Nose and Jocobson's Organ:** Introduction. Major Regions and Structures of the Reptilian Nose. Adult Anatomy of the Nasal Organs. Histology of the Nasal Organs. Embryology of the Nasal Organs. Nasal Glands. Discussion. Acknowledgements. References. IRWIN L. BAIRD: **The Anatomy of the Reptilian Ear:** Introduction. General Aural Anatomy of a "Typical" Lizard. The External and Middle Ear in Various Reptilian Groups. The Internal Ear of Various Reptilian Groups. Summary. Acknowledgements. Lists of Materials. References. ROBERT BARRETT with appendices by P. F. A. MADERSON and RICHARD M. MESZLER: **The Pit Organs of Snakes:** Introduction. Diffused Temperature Receptors. Radiant Heat Receptors. Unanswered Questions Requiring Further Research. References. Appendix 1: P. F. A. MADERSON: Appendix. Acknowledgements. References. Appendix 2: RICHARD M. MESZLER: Structure. Correlation of Structure and Function. References. CARL GANS and THOMAS S. PARSONS: **Taxonomic Literature on Reptiles:** Introduction. Assistance of Specialists. The Nature of the Taxonomic Literature. Literature Reviews and Special Journals. Listing by Groups. Regional Listings. Acknowledgements. References. Author Index-Subject Index.

1970, 374 pp., $16.50

VOLUME 3: MORPHOLOGY C—edited by CARL GANS.
Co-edited by THOMAS S. PARSONS

CONTENTS: HERBERT C. DESSAUER: **Blood Chemistry of Reptiles:** Physiological and Evolutionary Aspects: Introduction. Blood Letting and Handling. Composition of Blood Plasma. Composition of the Red Blood Cells. Blood Composition and Reptilian Systematics. Summary. Acknowledgements. References. MARIE-CHARLOTTE SAINT GIRONS: **Morphology of the Circulating Blood Cells:** Introduction. Erythrocytes. Eosinophilic Granulocytes. Basophilic Granulocytes. Azurophilic Granulocytes. Neutrophilic Granulocytes. Lymphocytes. Plasma Cells. Monocytes. Thrombocytes. Parasites in the Blood of Reptiles. Summary. References. R. DUGUY: **Numbers of Blood Cells and Their Variation:** Introduction. Techniques. Erythrocytes. Leucocytes. References. DALE E. BOCKMAN: **The Thymus:** Introduction. General Morphology. Embryonic Development. Histology. Fine Structure. Thymic Involution. Conclusion. Acknowledgements. References. HUBERT SAINT GIRONS: **The Pituitary Gland:** Introduction. The Hypothalamic-Neurohypophyseal Complex. The Adenhypophysis. Embryonic Development in Vascularization. Comparative Morphology of the Reptilian Hypophysis. Conclusions. References. W. GARDNER LYNN: **The Thyroid:** Introduction. Gross Morphology. Histology and Cytology. Embryology. Thyroid-Pituitary Relations. Biosynthesis of Thyroid Hormones. Seasonal Changes in the Thyroid. The Thyroid and Metabolism. The Thyroid and Ecdysis. The Thyroid and Growth and Differentiation. The Thyroid and Other Endocrine Organs. Miscellaneous Effects of Thyroid Hormone. Conclusion. References. NANCY B. CLARK: **The Parathyroid:** Introduction. Testudines. Crocodilia. Lepidosauria. References. MARFRED GABE: **The Adrenal:** Introduction. Embryonic Development. Macroscopic Anatomy. Microscopic Anatomy. Cytological and Histochemical Characteristics of Internal Cells. Cytological and Histochemical Characters of the Adrenal Cells. Histophysiology. Conclusion. References. MALCOLM R. MILLER and MICHAEL D. LAGIOS: **The Pancreas:** Introduction. Embryology. Topography and Structure. Histology. Conclusion. Acknowledgements. References. Author Index-Subject Index.

VOLUME 2, NUMBER 2

JUNE 1970

Herpetological Review

VOLUME 2, NUMBER 2. JUNE 1970

•CONTENTS

ARTICLES

4 SSAR MEETING IN KANSAS CITY, by James L. Vial.
A major symposium on anuran evolution is planned for the Thirteenth Annual Meeting, 27-30 August.

UNREVIEWED-UNEDITED COMMUNICATIONS

35 THE KARYOTYPE OF XENOPELTIS UNICOLOR, by C. J. Cole & H. G. Dowling.
The chromosomes of this taxonomically-isolated snake suggest boid relationships.

37 THE RELATIONSHIPS OF HYDRODYNASTES BICINCTUS and CYCLAGRAS GIGAS, by H. G. Dowling & F. W. Gibson. Similar morphological characters suggest a congeneric arrangement of these two Neotropical snakes.

BIBLIOGRAPHIC NOTE
****
Numbers 1 through 9 of HERPETOLOGICAL REVIEW appeared irregularly from 1967 through 1969.

A volume number, "Volume 2," was printed on the first issue to appear in 1970, as an indication of the REVIEW'S current status as a quarterly. Thus, numbers 1 through 9 (1967-1969) are included in Volume 1.

EDITORIAL

****

Delays in the makeup, printing, and mailing of HERPETOLOGICAL REVIEW 2(1) have prevented my knowing the reaction to its various innovations before this second number goes to press. Even so, a note has appeared in HERPETOLOGICA 26(1): 155, announcing the HR "Letters" section and the proposed "Unreviewed-Unedited" section. We hope that editors of other journals will accept the ideas as well.

As a start two papers are here published in this latter section. [It is my fervent hope that future issues of HR will not be so dowling-oriented.] Meanwhile, the REVIEW badly needs major articles, photographs of interesting animals, herpetologists, habitats, and happenings, book reviews, and about anything else you can think of. CONTRIBUTORS PLEASE COME FORWARD!! We will do anything but pay you.

****

Two other new departments are under consideration for future issues. One is an "Amphibian and Reptile Chromosomes" section, where concise information on the number and kind of chromosomes of various species could be recorded in tabular form [detailed descriptions can be given in the "Unedited" section, or elsewhere]. The other is a "Herpetologist's Record" section, where new geographic records, longevity records, emendations of previous records, and corrections of these and other kinds of information could be presented in concise form. Many records of this kind are not worth expanding into journal articles -- and the number of journals that will take such notes is rapidly shrinking. Yet, the information may be of great value to some, and should be made available promptly.

Both of these suggestions have grown out of conversations with Itzchak Gilboa and other associates. We believe that the provision of these additional places to record information (as distinguished from the published results of scientific studies) will fill important gaps in the present system of the retrieval and dissemination of herpetological information. -- HGD.

RECENT REPORT ON GALAPAGOS TORTOISES: SOME SURVIVE

Peter Pritchard ("Turtles of the World"; U Florida) spent some weeks in the Galapagos Islands recently, and perhaps we will have a detailed report from him some time. Meanwhile, we have some good news -- and we have some bad news.

A few weeks ago Roger Peterson called to say that he and Miguel Castro were in town, and would like to see me. It turned out that Roger was en route to Antarctica, and Miguel was on his way to Aldabra and the Seychelles.

Miguel Castro, for you who do not know, has spent some five years of his life working directly on the discovery, censusing, and preservation of the remaining colonies of giant tortoises in the Galapagos. Without doubt, he knows more of their status and prospects than any other man.

****

ROUGH CENSUS OF GALAPAGOS TORTOISES

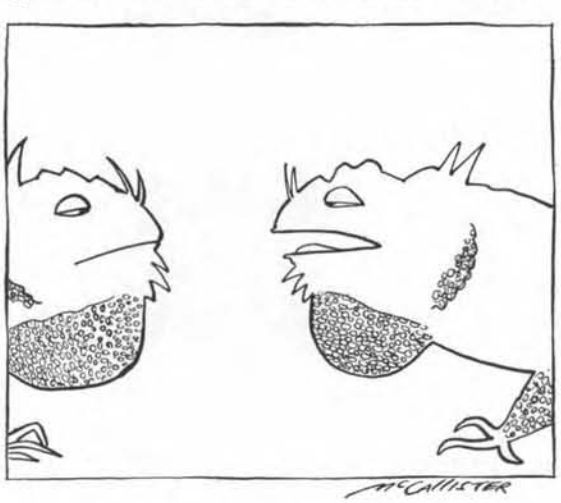
Geochelone elephantopus

****

ISLAND	NUMBER	BREEDING
Duncan	105	No*
Hood	5**	No
Isabela	Several colonies	Yes
James	120+	No***
Pinta	Extinct (ca. 1965)	--
San Cristobal	64	No***
Santa Cruz	****	Yes

Goats were introduced on Pinta in about 1953. * Young eaten by introduced rats. ** Three of these now at Darwin Research Station. *** Young eaten by pigs, dogs. **** Large number of marked individuals (I forgot to ask current count).

****



It was in 1962 that four of us (Robert Chase of Lafayette College, Rene Honegger of the Zurich Zoo, David Boyer of National Geographic, and I) first met this amazing home-grown naturalist. Others in the Galapagos might be more cosmopolitan, have better boats, or tell funnier stories, but it was Miguel who impressed us with his detailed knowledge of the migrations of birds and tortoises, the breeding habits of Marine and Land iguanas, and the status and distributions of the remaining colonies of the many rare and vanishing animals of that archipelago.

Thus, he was our choice as the first Conservation Officer of the Galapagos: a position subsidized for an original three years (and then extended) by the New York Zoological Society, and administered by the Charles Darwin Foundation for the Galapagos Isles. He worked in this position for almost five years.

During this time, he discovered and marked hundreds of tortoises on the various islands, reduced the goat herds that were threatening the extinction of endemic flora and fauna on some of the smaller islands, and hatched more than 100 tortoise eggs which he collected on Duncan Island -- representatives of a race that has not bred successfully in the wild (because of introduced Norway rats) in this century.

The program of tortoise conservation is badly threatened by Miguel's absence from the islands. No one else can offer the knowledge and leadership that he provided. I would guess, from my brief recent conversations with him, that his leaving was triggered by a number of things, including the resentment by several of his neighbors of his firm stand on the protection of the tortoises (killed, especially for their reservoir of fat, by fisherman) and the inviolability of the tortoise conservation areas which were set aside by the government of Ecuador. He also had some personal problems (his wife was killed under unexplained circumstances, during one of his absences). Perhaps not the least of his reasons, however, was frustration over the conservation policies (or lack of them) of the Foundation and the feeling that he was not backed strongly enough to carry out his job properly (e.g., there was often no boat available for him to use, to get from island to island).

We hope, nevertheless, that Miguel Castro will return to the islands that need him so much and thus reinvigorate the conservation program of the Darwin Foundation. -- HGD.

"As the lone surviving male and female, the perpetuation of our species depends on us. I'm willing to say the hell with it if you are."

SSAR MEETING IN

During August 27-30 the Society will be holding its thirteenth annual meeting at the University of Missouri-Kansas City in the "Heart of America".

Located on the southern edge of metropolitan Kansas City, Missouri, UMKC is an urban institution serving a community of nearly one million residents. Of the 9,800 students enrolled about 35 per cent are pursuing graduate or professional studies.

The Society will have full use of the campus facilities during this "between sessions" period of the academic calendar. Coincidentally, some of Kansas City's most exciting and entertaining activities are offered during this time of year.

All formal sessions of the meetings will be held in the University Student Center, one of the newer campus facilities. Housing will be provided at the UMKC dormitory and meals (including breakfast and lunch) will be provided in the Student Center. Additional lodging and meals are available at the numerous hotels and restaurants in Kansas City, at a great range in quality, atmosphere and, of course, price.

Tentative plans include the Board of Directors meeting Thursday evening and a social gathering aboard the Missouri River stern-wheeler "Border Starr" on Friday evening. A photographic exhibit is also planned. There will be three sessions of presented papers and three symposium sessions.

We are particularly pleased to announce the symposium on Evolutionary Biology of Anurans, which will be a principal feature of this year's meeting. Outstanding authorities, including scientists from Australia, Europe and South America will be presenting major papers or participating in the discussion sessions. The emphasis of this program will be upon broad biological perspectives, thus the topics and names of participants should be of immediate interest to all herpetologists.

This north-facing aerial view shows a portion of the UMKC campus. The University Student Center is located immediately above the circle drive. To the right, adjacent to the drive, is the Chemistry-Biology building. In the lower foreground is the converted mansion which currently houses many administrative offices. The Linda Hall Library of Science and Technology is just off the photograph at the lower left.

KANSAS CITY
27–30 AUGUST

Dr. W. Frank Blair (University of Texas) will present the introductory address and preside over the program. Among the participants will be James P. Bogart (University of Texas), William E. Duellman (University of Kansas), Richard Estes (Boston University), Sheldon I. Guttman (Miami University - Ohio), Robert F. Inger (Field Museum of Natural History, Chicago), John D. Lynch (University of Nebraska), David J. Merrell (University of Minnesota), George B. Rabb (Chicago Zoological Park), Stanley N. Salthe (Brooklyn College, New York), Jay M. Savage (University of Southern California), Arne Schiotz (Danmarks Akvarium, Denmark), Priscilla Starrett (University of Southern California), Ian Straughn (University College of Townsville, Australia), Joseph A. Tihen (University of Notre Dame), Linda Trueb (University of Kansas), and Richard Wasserzug (University of California at Berkeley). We have not yet received definite commitments from the invited South American scientists.

***

Further details of the program, registration, accommodations and transportation will be included in a future announcement being mailed to all members. Any inquiries may be addressed to the chairman of the meeting: James L. Vial, Department of Biology, University of Missouri-Kansas City, Kansas City, Missouri 64110.

***

EVOLUTIONARY BIOLOGY OF ANURANS
PROGRAM

INTRODUCTION: MAJOR PROBLEMS IN ANURAN EVOLUTION.

SESSION I

1. Origins and Early Evolution of Anurans.
2. Evolutionary Trends in Anuran Osteology.
3. Transition from Archaic to Advanced Frogs.
4. Biochemical Trends in Anuran Evolution.

Panel Discussion

SESSION II

5. Evolutionary Biogeography.
6. Evolution of Mating Behavior.
7. Evolution of Reproductive Adaptations.
8. Evolutionary Patterns in Larval Morphology.
9. Ecological and Behavioral Patterns of Anuran Larvae.

Panel Discussion

SESSION III

10. Evolution of Mating Calls: Bioacoustical Considerations.
11. Evolution of Mating Calls: Ecological Considerations.
12. Evolution of Karyotypes.
13. Populational Evolution of Anurans.

Panel Discussion

SUMMATION PANEL

Registration and all formal sessions of the 13th annual SSAR meeting will convene in the Student Center.

book review

DISTRIBUTIONAL SURVEY: MARYLAND AND THE DISTRICT OF COLUMBIA. By Herbert S. Harris, Jr. Bull. Md. Herp. Soc. 5(4): 97-161, December 1969, 89 maps, $2.

Although political boundaries per se are of little or no interest to biogeographers, ecologists, and other students of distribution, the "state list" has always been a handy way for local workers to present what may well be a wealth of distributional information. Such surveys are particularly useful if they emphasize geomorphological subdivisions, faunal areas, and drainage patterns for aquatic forms, and include detailed maps.

The state of Maryland (plus the District of Columbia) occupies a position of considerable interest to herpetogeographers. Not only does one encounter portions of three major geomorphic regions within its boundaries (Appalachian, Piedmont and Coastal Plain), and elements of two major drainage systems (Ohio and Atlantic Coast), but two reptile species appear to reach the southernmost limit of their major, non-relictual range in the state and adjacent Delaware, and at least six amphibians and reptiles reach similar northernmost limits there.

In this latest distributional survey of the herpetofauna of Maryland and D. C., Herbert S. Harris, Jr., has scrupulously tried to track down every locality record which has turned up in the decade since publication of Cooper's 1960 survey, has added some records previously missed, and, more importantly, has meticulously plotted all of these on annotated distribution maps for each species. The result is the most up-to-date and detailed visual picture of the distribution of Maryland reptiles in a quarter of a century, and the only such picture ever presented for the amphibians. The survey also includes a list of amphibians and reptiles of the area being considered, a discussion of erroneous records and possible additions, county and physiographic province lists, a physiographic map of the state, and a bibliography.

Criticisms of the paper are mostly, but not completely, minor. The usual typographical errors which one finds even in more pretentious publications are present, but not overly distracting except to proponents of the picayune. Some slight inconsistency is noted in use of the map symbols indicating specimens examined, etc., and in the citing of authorities for some notable records and comments and not for others. The annotations include some interesting and disturbing facts related to distribution, such as the filling in of one of the two known Western Shore breeding ponds of Ambystoma t. tigrinum for construction of a golf course, and a plea for conservation of Cryptobranchus whose numbers are apparently dwindling in Maryland. It is a little difficult to understand, however, the inclusion of occasional comments on normal breeding habits of some species (but not all) in a distributional survey.

A few of the statements are questionable. For example, Pseudotriton m. montanus is said to be "Found commonly in association with springs". In truth this almost exclusively Coastal Plain salamander is rarely, if ever, associated with springs in Maryland, although elsewhere in its range it may be Piedmont in distribution and live in such situations. Opheodrys aestivus is said to "encroach the Piedmont via rivers," and, similarly, Lampropeltis g. getulus "encroaches the Eastern Piedmont via river systems". It is not being finicky to point out that what is apparently meant here is encroachment by range expansion into lowland river valleys, not "via rivers" or "river systems", which implies swimming or passive transport upstream! No comment is made on an isolated record for O. aestivus in the Appalachian Plateau. Lampropeltis d. triangulum "intergrades with L. d. temporalis along the Fall Line, hence this criteria (sic) is used here to separate the subspecies". No area of intergradation is shown on the map, despite the fact that these subspecies intergrade over a wide area on both sides of the Fall Line. The allegation is made that Storeria d. dekayi is "Most abundant around populated areas". A more likely statement would be that compression of suitable habitat in such areas results in greater population density, if indeed the claim can be quantitatively substantiated at all. Storeria o. occipitomaculata is a very abundant snake on the Alleghany Plateau, "where melanistic individuals are not uncommon". Although the whole comment is rather much beside the point in this context, the Alleghany Plateau specimens of this snake in Maryland are almost exclusively dark, and it is the light specimens which are seldom seen there. This may well be an ecophenotypic response and an argument against genetic melanism. The bibliography, while not exactly "complete", is still extensive and very useful. A drainage system map and a map of faunal areas would have been useful, with appropriate distributional comments.

Despite these criticisms, this publication is a very good summary of our current knowledge of the distribution of amphibians and reptiles in an important sector of the Atlantic Coast. Herb Harris and the Maryland Herpetological Society are to be commended for their efforts.

LATE NEWS

The 50th Annual Meeting of the AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS, held in New Orleans, 26-30 March, was probably the best-attended in the Society's history. More than 400 persons registered. Of the 164 papers listed on the program, 91 were herpetological. [Compare "Fifty Years Ago"].

"Two falls out of three, O.K.?"

The New Yorker Magazine, Inc.

The ASSOCIATION OF SOUTHEASTERN BIOLOGISTS held its 31st Annual Meeting at Florida Southern College, Lakeland, on 1-4 April. Nine herpetological papers were presented in a special "Ichthyology and Herpetology" section; another five were given in the section on "Animal Physiology".

The SOUTHWESTERN ASSOCIATION OF NATURALISTS held its 17th Annual Meeting at College Station, Texas, on 23-26 April. Three of the eight herpetological papers dealt with parthenogenic species of Whiptail lizards, Cnemidophorus.

INDIVIDUALS AND INSTITUTIONS

****

A Reuters dispatch of 5 March reveals that "Australian Customs men have smashed an international snake-smuggling ring". The arrest of ten men in Sydney, Bundaberg, and Townsville is believed to have stopped the illegal importation of venomous snakes from the United States, Canada, India, and the Pacific Islands. Some snakes had been sent by mail.

JAMES A. OLIVER (previous Director of the Bronx Zoo, recent Director of the American Museum of Natural History) has rejoined the New York Zoological Society (after a ten-year lapse) as Director of the New York Aquarium.... LINDA TREUB (frog anatomy, U Kansas) has announced the birth of a daughter, Dana Kirsten Duellman, on 11 March.... JAREN HORSLEY (formerly of the Oklahoma City Zoo) joined the National Zoological Park as Curator of Reptiles in 1969.... KEVIN BOWLER (also formerly of the Oklahoma City Zoo) has recently become Assistant to the Director of the Philadelphia Zoo (ROGER CONANT).

ROBERT MERTENS (herpetologist & Director Emeritus of the Senckenberg Museum) celebrated his 76th birthday on 12 January.... FRED R. CAGLE (1915-1968) was the first recipient (posthumous) of the Meritorious Award for Excellence in Scientific Communication, presented by the Council of Biology Editors, 19 May 1969.

MAX A. NICKERSON (Arkansas State U) and others are studying Cryptobranchus alleganiensis bishopi.... EDWARD WORTHAM (ASU) is studying the serum proteins of that salamander, and CHARLES E. MAYS (DePauw U) is aiding in a tagging study of it.... JIM GRISSOM (ASU) is studying serum proteins of some plethodontid salamanders.... JAMES A. HUTCHISON (ASU) and Dr. Nickerson are studying the distribution of Basidiobolus ranarum, a common saprobe in salamanders, frogs, and lizards, that is suspected as an etiologic agent of Phycomycosis in humans.

EUGENE S. GAFFNEY (turtle taxonomy) will

become Assistant Curator in the Department of Vertebrate Paleontology, American Museum of Natural History, on 1 July.... STEVEN C. ANDERSON (lizard taxonomy; Calif. Acad. Sci.) will move to University of the Pacific, Stockton, Calif., as of 1 August.

50 YEARS AGO

****

The Fifth Annual Meeting of the AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS was held in Room 43, U. S. National Museum, Washington, D. C., on Friday, May 14, 1920.

Ten members were present at the business meeting. Eleven papers were read, six of them herpetological. Perhaps the two of greatest significance were: "The genetic relations of the Salientia," by G. K. Noble, and "The correlation of lunglessness in salamanders with a mountain-brook habitat," by Inez W. Wilder and E. R. Dunn.

CURRENT HERPETOLOGICAL TITLES, X: 1969 - 1970

Herpetological Information Search Systems
American Museum of Natural History
New York, N. Y. 10024

In the last two and a half years we brought to your attention some 10,000 current titles in the pages of this journal.

The titles of papers appearing in our lists were obtained by regular scanning of about 2500 journals directly and over 1000 indirectly, through secondary sources such as Chemical Abstracts-Biochemical sections, Current Contents, publishers' catalogs, and several others. Theses in English also appear, coming from such sources as Dissertation Abstracts and various academic publications. Abstracts of papers presented at various meetings and symposia are included. This list contains the abstracts of papers presented at the ASIH, SSAR and the 2nd Int. Symp. Anim. Plant Toxins among others. We note the absence of abstracts from the Herpetological League meeting. The coverage of books and theses in languages other than English is improving because a larger number of our colleagues bring those titles to our attention. Some copies have been mailed directly to us for inclusion in our lists. However, we would still appreciate being made aware of new books, reports, and non-English theses especially.

We realize that many of the titles listed are marginal to the field of herpetology as customarily defined. Many are published in journals of physiology, pharmacology, cytology, or embryology. Others are from medical journals, state fish and game publications, or pet animal journals. Thus, they are not aimed at an audience of herpetologists. All of them, however, deal in some way with amphibians and reptiles. As such, they may be of some interest to at least some readers of HERPETOLOGICAL REVIEW. It seems better to let the reader make the selection from the list, rather than one of our small group deciding that this paper or that -- or this kind of paper -- is of no interest to anyone.

Our present policy, then, is to list the title of any paper that is concerned with a member of a Recent order of amphibians or reptiles.

Except for the omission of extinct orders, our list is comparable with that of the Amphibia and Reptilia sections of the Zoological Record, though ours is more comprehensive and considerably more current.

This tenth list contains titles of books and articles that have come to our attention during the period 6 January 1970 through 28 April 1970. The list is divided into two separate, alphabetically arranged sections: one for titles published in 1969, and one for titles published in 1970.

Acknowledgements. This list was prepared by the HISS staff: H. G. Dowling, I. Gilboa, I. Palser, and T. Shaman. J. A. Peters of the U. S. National Museum has continued to provide a welcome back-up program to our search of the literature, and G. J. Jacobs of NASA has kept us informed of the many publications and translations resulting from the United States space efforts. We also wish to thank the many individuals who have sent us early copies of reprints for inclusion here.

Members of the Herpetology Department and the Library staff of the Museum have continued to aid our efforts. No commercial computer service yet offers all of the facilities that we need, however, and we continue to rely on the advice and aid of James E. Bradley of the University of Rhode Island Computer Laboratory. We are grateful to all of these individuals and institutions for their help.

This is contribution Number 20 of the Genera of Reptiles Project, which is supported by the Information Services Program of the National Science Foundation (NSF GN-707).
